6LoWPAN Generic Compression of Headers and Header-like Payloads (GHC)
draft-ietf-6lo-ghc-05

Abstract

This short specification provides a simple addition to 6LoWPAN Header Compression that enables the compression of generic headers and header-like payloads, without a need to define a new header compression scheme for each new such header or header-like payload.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 23, 2015.

1. Introduction

1.1. The Header Compression Coupling Problem

6LoWPAN-HC [RFC6282] defines a scheme for header compression in 6LoWPAN [RFC4944] packets. As with most header compression schemes, a new specification is needed for every new kind of header that needs to be compressed. In addition, [RFC6282] does not define an extensibility scheme like the ROHC profiles defined in ROHC [RFC3095] [RFC5795]. This leads to the difficult situation that 6LoWPAN-HC tended to be reopened and reexamined each time a new header receives consideration (or an old header is changed and reconsidered) in the 6LoWPAN/roll/CoRE cluster of IETF working groups. While [RFC6282] finally got completed, the underlying problem remains unsolved.

The purpose of the present contribution is to plug into [RFC6282] as is, using its NHC (next header compression) concept. We add a slightly less efficient, but vastly more general form of compression for headers of any kind and even for header-like payloads such as those exhibited by routing protocols, DHCP, etc.: Generic Header Compression (GHC). The objective is an extremely simple specification that can be defined on a single page and implemented in a small number of lines of code, as opposed to a general data compression scheme such as that defined in [RFC1951].

1.2. Compression Approach

The basic approach of GHC's compression function is to define a bytecode for LZ77-style compression [LZ77]. The bytecode is a series of simple instructions for the decompressor to reconstitute the uncompressed payload. These instructions include:

- o appending bytes to the reconstituted payload that are literally given with the instruction in the compressed data
- o appending a given number of zero bytes to the reconstituted payload
- o appending bytes to the reconstituted payload by copying a contiguous sequence from the payload being reconstituted ("backreferencing")
- o an ancillary instruction for setting up parameters for the backreferencing instruction in "decompression variables"
- o a stop code (optional, see Section 3.2)

The buffer for the reconstituted payload ("destination buffer") is prefixed by a predefined dictionary that can be used in the backreferencing as if it were a prefix of the payload. This predefined dictionary is built from the IPv6 addresses of the packet being reconstituted, followed by a static component, the "static dictionary".

As usual, this specification defines the decompressor operation in detail, but leaves the detailed operation of the compressor open to implementation. The compressor can be implemented as with a classical LZ77 compressor, or it can be a simple protocol encoder that just makes use of known compression opportunities.

1.3. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

The term "byte" is used in its now customary sense as a synonym for "octet".

Terms from [RFC7228] are used in Section 5.

1.4. Notation

This specification uses a trivial notation for code bytes and the bitfields in them, the meaning of which should be mostly obvious. More formally, the meaning of the notation is:

Potential values for the code bytes themselves are expressed by templates that represent 8-bit most-significant-bit-first binary numbers (without any special prefix), where 0 stands for 0, 1 for 1, and variable segments in these code byte templates are indicated by sequences of the same letter such as kkkkkkk or ssss, the length of which indicates the length of the variable segment in bits.

In the notation of values derived from the code bytes, 0b is used as a prefix for expressing binary numbers in most-significant-bit first notation (akin to the use of 0x for most-significant-digit-first hexadecimal numbers in the C programming language). Where the above-mentioned sequences of letters are then referenced in such a binary number in the text, the intention is that the value from these bitfields in the actual code byte be inserted.

Example: The code byte template

101nssss

stands for a byte that starts (most-significant-bit-first) with the bits 1, 0, and 1, and continues with five variable bits, the first of which is referenced as "n" and the next four are referenced as "ssss". Based on this code byte template, a reference to

0b0ssss000

means a binary number composed from a zero bit, the four bits that are in the "ssss" field (for 101nssss, the four least significant bits) in the actual byte encountered, kept in the same order, and three more zero bits.

2. 6LoWPAN-GHC

The format of a GHC-compressed header or payload is a simple bytecode. A compressed header consists of a sequence of pieces, each of which begins with a code byte, which may be followed by zero or more bytes as its argument. Some code bytes cause bytes to be laid out in the destination buffer, some simply modify some decompression variables.

At the start of decompressing a header or payload within a L2 packet (= fragment), the decompression variables "sa" and "na" are initialized as zero.

The code bytes are defined as follows (Table 1):

| code byte | Action | Argument |
|-----------|--|-----------------|
| 0kkkkkkk | Append k = 0b0kkkkkkk bytes of data in the bytecode argument (k < 96) | k bytes of data |
| 1000nnnn | Append 0b0000nnnn+2 bytes of zeroes | |
| 10010000 | STOP code (end of compressed data, see Section 3.2) | |
| 101nssss | Set up extended arguments for a backreference: sa += 0b0ssss000, na += 0b0000n000 | |
| 11nnnnkkk | Backreference: n = na+0b00000nnn+2; s = 0b00000kkk+sa+n; append n bytes from previously output bytes, starting s bytes to the left of the current output pointer; set sa = 0, na = 0 | |

Table 1: Bytecodes for generic header compression

Note that the following bit combinations are reserved at this time: 011xxxxx, and 1001nnnn (where 0b0000nnnn > 0).

For the purposes of the backreferences, the expansion buffer is initialized with a predefined dictionary, at the end of which the reconstituted payload begins. This dictionary is composed of the source and destination IPv6 addresses of the packet being reconstituted, followed by a 16-byte static dictionary (Figure 1).

These 48 dictionary bytes are therefore available for backreferencing, but not copied into the final reconstituted payload.

```
16 fe fd 17 fe fd 00 01 00 00 00 00 00 01 00 00
```

Figure 1: The 16 bytes of static dictionary (in hex)

3. Integrating 6LoWPAN-GHC into 6LoWPAN-HC

6LoWPAN-GHC plugs in as an NHC format for 6LoWPAN-HC [RFC6282].

3.1. Compressing payloads (UDP and ICMPv6)

GHC is by definition generic and can be applied to different kinds of packets. Many of the examples given in Appendix A are for ICMPv6 packets; a single NHC value suffices to define an NHC format for ICMPv6 based on GHC (see below).

In addition it is useful to include an NHC format for UDP, as many headerlike payloads (e.g., DHCPv6, DTLS) are carried in UDP. [RFC6282] already defines an NHC format for UDP (11110CPP). GHC uses an analogous NHC byte formatted as shown in Figure 2. The difference to the existing UDP NHC specification is that for 0b11010cpp NHC bytes, the UDP payload is not supplied literally but compressed by 6LoWPAN-GHC.

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 1 | 0 | C | P | |

Figure 2: NHC byte for UDP GHC (to be allocated by IANA)

To stay in the same general numbering space, we use 0b11011111 as the NHC byte for ICMPv6 GHC (Figure 3).

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 |

Figure 3: NHC byte for ICMPv6 GHC (to be allocated by IANA)

3.2. Compressing extension headers

Compression of specific extension headers is added in a similar way (Figure 4) (however, probably only EID 0 to 3 need to be assigned). As there is no easy way to extract the length field from the GHC-

encoded header before decoding, this would make detecting the end of the extension header somewhat complex. The easiest (and most efficient) approach is to completely elide the length field (in the same way NHC already elides the next header field in certain cases) and reconstruct it only on decompression. To serve as a terminator for the extension header, the reserved bytecode 0b10010000 has been assigned as a stop marker. Note that the stop marker is only needed for extension headers, not for the final payloads discussed in the previous subsection, the decompression of which is automatically stopped by the end of the packet.

Figure 4: NHC byte for extension header GHC

3.3. Indicating GHC capability

The 6LoWPAN baseline includes just [RFC4944], [RFC6282], [RFC6775] (see [I-D.bormann-6lo-6lowpan-roadmap]). To enable the use of GHC towards a neighbor, a 6LoWPAN node needs to know that the neighbor implements it. While this can also simply be administratively required, a transition strategy as well as a way to support mixed networks is required.

One way to know a neighbor does implement GHC is receiving a packet from that neighbor with GHC in it ("implicit capability detection"). However, there needs to be a way to bootstrap this, as nobody ever would start sending packets with GHC otherwise.

To minimize the impact on [RFC6775], we define an ND option 6LoWPAN Capability Indication (6CIO), as illustrated in Figure 5. (For the fields marked by an underscore in Figure 5, see Section 3.4.)

Figure 5: 6LoWPAN Capability Indication Option (6CIO)

The G bit indicates whether the node sending the option is GHC capable.

Once a node receives either an explicit or an implicit indication of GHC capability from another node, it may send GHC-compressed packets to that node. Where that capability has not been recently confirmed, similar to the way PLPMTUD [RFC4821] finds out about changes in the network, a node SHOULD make use of NUD (neighbor unreachability detection) failures to switch back to basic 6LoWPAN header compression [RFC6282].

3.4. Using the 6CIO Option

The 6CIO option will typically only be ever sent in 6LoWPAN-ND RS packets (which cannot itself be GHC compressed unless the host desires to limit itself to talking to GHC capable routers). The resulting 6LoWPAN-ND RA can then already make use of GHC and thus indicate GHC capability implicitly, which in turn allows both nodes to use GHC in the 6LoWPAN-ND NS/NA exchange.

6CIO can also be used for future options that need to be negotiated between 6LoWPAN peers; an IANA registry is used to assign the flags. Bits marked by underscores in Figure 5 are unassigned and available for future assignment. They MUST be sent as zero and MUST be ignored on reception until assigned by IANA. Length values larger than 1 MUST be accepted by implementations in order to enable future extensions; the additional bits in the option are then deemed unassigned in the same way. For the purposes of the IANA registry, the bits are numbered in most-significant-bit-first order from the 16th bit of the option onward: the 16th bit is flag number 0, the 31st bit (the G bit) is flag number 15, up to the 63rd bit for flag number 47. (Additional bits may also be used by a follow-on version of this document if some bit combinations that have been left unassigned here are then used in an upward compatible manner.)

Flag numbers 0 to 7 are reserved for experiments. They MUST NOT be used for actual deployments.

Where the use of this option by other specifications or by experiments is envisioned, the following items have to be kept in mind:

- o The option can be used in any ND packet.
- o Specific bits are set in the option to indicate that a capability is present in the sender. (There may be other ways to infer this information, as is the case in this specification.) Bit combinations may be used as desired. The absence of the capability `_indication_` is signaled by setting these bits to zero; this does not necessarily mean that the capability is absent.

- o The intention is not to modify the semantics of the specific ND packet carrying the option, but to provide the general capability indication described above.
- o Specifications have to be designed such that receivers that do not receive or do not process such a capability indication can still interoperate (presumably without exploiting the indicated capability).
- o The option is meant to be used sparsely, i.e. once a sender has reason to believe the capability indication has been received, there no longer is a need to continue sending it.

4. IANA considerations

[This section to be removed/replaced by the RFC Editor.]

In the IANA registry for the "LOWPAN_NHC Header Type" (in the "IPv6 Low Power Personal Area Network Parameters"), IANA is requested to add the assignments in Figure 6.

| | |
|--------------------------------|-----------|
| 10110IIN: Extension header GHC | [RFCthis] |
| 11010CPP: UDP GHC | [RFCthis] |
| 11011111: ICMPv6 GHC | [RFCthis] |

Figure 6: IANA assignments for the NHC byte

IANA is requested to allocate an ND option number for the "6LoWPAN Capability Indication Option (6CIO)" ND option format in the Registry "IPv6 Neighbor Discovery Option Formats" [RFC4861].

IANA is requested to create a subregistry for "6LoWPAN capability bits" within the "Internet Control Message Protocol version 6 (ICMPv6) Parameters". The bits are assigned by giving their numbers as small non-negative integers as defined in section Section 3.4, preferably in the range 0..47. The policy is "IETF Review" or "IESG Approval" [RFC5226]. The initial content of the registry is as in Figure 7:

| | |
|--------------------------------|-----------|
| 0..7: reserved for experiments | [RFCthis] |
| 8..14: unassigned | |
| 15: GHC capable bit (G bit) | [RFCthis] |
| 16..47: unassigned | |

Figure 7: IANA assignments for the 6LoWPAN capability bits

5. Security considerations

The security considerations of [RFC4944] and [RFC6282] apply. As usual in protocols with packet parsing/construction, care must be taken in implementations to avoid buffer overflows and in particular (with respect to the back-referencing) out-of-area references during decompression.

One additional consideration is that an attacker may send a forged packet that makes a second node believe a third victim node is GHC-capable. If it is not, this may prevent packets sent by the second node from reaching the third node (at least until robustness features such as those discussed in Section 3.3 kick in).

No mitigation is proposed (or known) for this attack, except that a victim node that does implement GHC is not vulnerable. However, with unsecured ND, a number of attacks with similar outcomes are already possible, so there is little incentive to make use of this additional attack. With secured ND, 6CIO is also secured; nodes relying on secured ND therefore should use 6CIO bidirectionally (and limit the implicit capability detection to secured ND packets carrying GHC) instead of basing their neighbor capability assumptions on receiving any kind of unprotected packet.

As with any LZ77 scheme, decompression bombs (compressed packets crafted to expand so much that the decompressor is overloaded) are a problem. An attacker cannot send a GHC decompressor into a tight loop for too long, because the MTU will be reached quickly. Some amplification of an attack from inside the compressed link is possible, though. Using a constrained node in a constrained network as a DoS attack source is usually not very useful, though, except maybe against other nodes in that constrained network. The worst case for an attack to the outside is a not-so-constrained device using a (typically not-so-constrained) edge router to attack by forwarding out of its Ethernet interface. The worst-case amplification of GHC is 17, so an MTU-size packet can be generated from a 6LoWPAN packet of 76 bytes. The 6LoWPAN network is still constrained, so the amplification at the edge router turns an entire 250 kbit/s 802.15.4 network (assuming a theoretical upper bound of 225 kbit/s throughput to a single-hop adjacent node) into a 3.8 Mbit/s attacker.

The amplification may be more important inside the 6LoWPAN, if there is a way to obtain reflection (otherwise the packet is likely to simply stay compressed on the way and do little damage), e.g., by pinging a node using a decompression bomb, somehow keeping that node from re-compressing the ping response (which would probably require something more complex than simple runs of zeroes, so the worst-case

amplification is likely closer to 9). Or, if there are nodes that do not support GHC, those can be attacked via a router that is then forced to decompress.

All these attacks are mitigated by some form of network access control.

In a 6LoWPAN stack, sensitive information will normally be protected by transport or application (or even IP) layer security, which are all above the adaptation layer, leaving no sensitive information to compress at the GHC level. However, a 6LoWPAN deployment that entirely depends on MAC layer security may be vulnerable to attacks that exploit redundancy information disclosed by compression to recover information about secret values. The attacker would need to be in radio range to observe the compressed packets. Since compression is stateless, the attacker would need to entice the party sending the secret value to also send some value controlled (or at least usefully varying and knowable) by the attacker in (what becomes the first adaptation layer fragment of) the same packet. This attack is fully mitigated by not exposing secret values to the adaptation layer, or by not using GHC in deployments where this is done.

6. Acknowledgements

Colin O'Flynn has repeatedly insisted that some form of compression for ICMPv6 and ND packets might be beneficial. He actually wrote his own draft, [I-D.oflynn-6lowpan-icmphc], which compresses better, but addresses basic ICMPv6/ND only and needs a much longer spec (around 17 pages of detailed spec, as compared to the single page of core spec here). This motivated the author to try something simple, yet general. Special thanks go to Colin for indicating that he indeed considers his draft superseded by the present one.

The examples given are based on pcap files that Colin O'Flynn, Owen Kirby, Olaf Bergmann and others provided.

Using these pcap files as a corpus, the static dictionary was developed, and the bit allocations validated, based on research by Sebastian Dominik.

Erik Nordmark provided input that helped shaping the 6CIO option. Thomas Bjorklund proposed simplifying the predefined dictionary.

Yoshihiro Ohba insisted on clarifying the notation used for the definition of the bytecodes and their bitfields. Ulrich Herberg provided some additional review and suggested expanding the introductory material, and with Hannes Tschofenig and Brian Haberman

he helped come up with the IANA policy for the "6LoWPAN capability bits" assignments in the 6CIO option.

The IESG reviewers Richard Barnes and Stephen Farrell have contributed issues to the security considerations section; they and Barry Leiba, as well as GEN-ART reviewer Vijay K. Gurbani also have provided editorial improvements.

Figure 9: A longer RPL example

Similarly, Figure 10 shows an RPL DAO message. One of the embedded addresses is copied right out of the pseudo-header, the other one is effectively converted from global to local by providing the prefix FE80 literally, inserting a number of nulls, and copying (some of) the IID part again out of the pseudo-header. Note that a simple implementation would probably emit fewer nulls and copy the entire IID; there are multiple ways to encode this 50-byte payload into 27 bytes.

Was 48 bytes; compressed to 27 bytes, compression factor 1.78

Figure 12: An ND neighbor advertisement

Figure 13 shows the compression of an ND router solicitation. Note that the relatively good compression is not caused by the many zero bytes in the link-layer address of this particular capture (which are unlikely to occur in practice): 7 of these 8 bytes are copied from the pseudo-header (the 8th byte cannot be copied as the universal/local bit needs to be inverted).

Figure 14: An ND router advertisement

Figure 15 shows the compression of a DTLS application data packet with a net payload of 13 bytes of cleartext, and 8 bytes of

authenticator (note that the IP header is not relevant for this example and has been set to 0). This makes good use of the static dictionary, and is quite effective crunching out the redundancy in the TLS_PSK_WITH_AES_128_CCM_8 header, leading to a net reduction by 15 bytes.

IP header:

```
00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
