HTTP Alternative Services
draft-ietf-httpbis-alt-svc-09

Abstract

This document specifies "alternative services" for HTTP, which allow an origin's resources to be authoritatively available at a separate network location, possibly accessed with a different protocol configuration.

Editorial Note (To be removed by RFC Editor)

Discussion of this draft takes place on the HTTPBIS working group mailing list (ietf-http-wg@w3.org), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/>.

Working Group information can be found at <https://tools.ietf.org/wg/httpbis/> and <http://httpwg.github.io/>; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions>.

The changes in this draft are summarized in Appendix A.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 20, 2016.

1. Introduction

HTTP [RFC7230] conflates the identification of resources with their location. In other words, "http://" (and "https://") URLs are used to both name and find things to interact with.

In some cases, it is desirable to separate identification and location in HTTP; keeping the same identifier for a resource, but interacting with it at a different location on the network.

For example:

- An origin server might wish to redirect a client to a different server when it is under load, or it has found a server in a location that is more local to the client.
- An origin server might wish to offer access to its resources using a new protocol (such as HTTP/2, see [RFC7540]) or one using improved security (such as Transport Layer Security (TLS), see [RFC5246]).
- An origin server might wish to segment its clients into groups of capabilities, such as those supporting Server Name Indication (SNI, see Section 3 of [RFC6066]) and those not supporting it, for operational purposes.

This specification defines a new concept in HTTP, "Alternative Services", that allows an origin server to nominate additional means of interacting with it on the network. It defines a general framework for this in Section 2, along with specific mechanisms for advertising their existence using HTTP header fields (Section 3) or HTTP/2 frames (Section 4), plus a way to indicate that an alternative service was used (Section 5).

It also endorses the status code 421 (Misdirected Request) (Section 6) that origin servers (or their nominated alternatives) can use to indicate that they are not authoritative for a given origin, in cases where the wrong location is used.

1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This document uses the Augmented BNF defined in [RFC5234] along with the "#rule" extension defined in Section 7 of [RFC7230]. The rules below are defined in [RFC5234], [RFC7230], and [RFC7234]:

2. Alternative Services Concepts

This specification defines a new concept in HTTP, the "alternative service". When an origin (see [RFC6454]) has resources that are accessible through a different protocol / host / port combination, it is said to have an alternative service available.

An alternative service can be used to interact with the resources on an origin server at a separate location on the network, possibly using a different protocol configuration. Alternative services are considered authoritative for an origin’s resources, in the sense of [RFC7230], Section 9.1.

For example, an origin:

("http", "www.example.com", "80")

might declare that its resources are also accessible at the alternative service:

("h2", "new.example.com", "81")

By their nature, alternative services are explicitly at the granularity of an origin; i.e., they cannot be selectively applied to resources within an origin.

Alternative services do not replace or change the origin for any given resource; in general, they are not visible to the software "above" the access mechanism. The alternative service is essentially alternative routing information that can also be used to reach the origin in the same way that DNS CNAME or SRV records define routing information at the name resolution level. Each origin maps to a set of these routes -- the default route is derived from the origin itself and the other routes are introduced based on alternative-protocol information.

Furthermore, it is important to note that the first member of an alternative service tuple is different from the "scheme" component of an origin; it is more specific, identifying not only the major version of the protocol being used, but potentially communication
options for that protocol.

This means that clients using an alternative service can change the host, port and protocol that they are using to fetch resources, but these changes MUST NOT be propagated to the application that is using HTTP; from that standpoint, the URI being accessed and all information derived from it (scheme, host, port) are the same as before.

Importantly, this includes its security context; in particular, when TLS [RFC5246] is used to authenticate, the alternative service will need to present a certificate for the origin’s host name, not that of the alternative. Likewise, the Host header field ([RFC7230], Section 5.4) is still derived from the origin, not the alternative service (just as it would if a CNAME were being used).

The changes MAY, however, be made visible in debugging tools, consoles, etc.

Formally, an alternative service is identified by the combination of:

- An Application Layer Protocol Negotiation (ALPN) protocol name, as per [RFC7301]
- A host, as per [RFC3986], Section 3.2.2
- A port, as per [RFC3986], Section 3.2.3

The ALPN protocol name is used to identify the application protocol or suite of protocols used by the alternative service. Note that for the purpose of this specification, an ALPN protocol name implicitly includes TLS in the suite of protocols it identifies, unless specified otherwise in its definition. In particular, the ALPN name "http/1.1", registered by Section 6 of [RFC7301], identifies HTTP/1.1 over TLS.

Additionally, each alternative service MUST have:

- A freshness lifetime, expressed in seconds; see Section 2.2

There are many ways that a client could discover the alternative service(s) associated with an origin. This document describes two such mechanisms: an HTTP header field (Section 3) and an HTTP/2 frame type (Section 4).

The remainder of this section describes requirements that are common to alternative services, regardless of how they are discovered.
2.1. Host Authentication

Clients MUST NOT use alternative services with a host that is different than the origin’s without strong server authentication; this mitigates the attack described in Section 9.2. One way to achieve this is for the alternative to use TLS with a certificate that is valid for that origin.

For example, if the origin’s host is "www.example.com" and an alternative is offered on "other.example.com" with the "h2" protocol, and the certificate offered is valid for "www.example.com", the client can use the alternative. However, if "other.example.com" is offered with the "h2c" protocol, the client cannot use it, because there is no mechanism in that protocol to establish strong server authentication.

2.2. Alternative Service Caching

Mechanisms for discovering alternative services also associate a freshness lifetime with them; for example, the Alt-Svc header field uses the "ma" parameter.

Clients can choose to use an alternative service instead of the origin at any time when it is considered fresh; see Section 2.4 for specific recommendations.

Clients with existing connections to an alternative service do not need to stop using it when its freshness lifetime ends; i.e., the caching mechanism is intended for limiting how long an alternative service can be used for establishing new connections, not limiting the use of existing ones.

Alternative services are fully authoritative for the origin in question, including the ability to clear or update cached alternative service entries, extend freshness lifetimes, and any other authority the origin server would have.

When alternative services are used to send a client to the most optimal server, a change in network configuration can result in cached values becoming suboptimal. Therefore, clients SHOULD remove from cache all alternative services that lack the "persist" flag with the value "1" when they detect such a change (when information about network state is available).

2.3. Requiring Server Name Indication

A client MUST only use a TLS-based alternative service if the client also supports TLS Server Name Indication (SNI). This supports the
conservation of IP addresses on the alternative service host.

Note that the SNI information provided in TLS by the client will be that of the origin, not the alternative (as will the Host HTTP header field-value).

2.4. Using Alternative Services

By their nature, alternative services are OPTIONAL: clients do not need to use them. However, it is advantageous for clients to behave in a predictable way when they are used by servers (e.g., for load balancing).

Therefore, if a client becomes aware of an alternative service, the client SHOULD use that alternative service for all requests to the associated origin as soon as it is available, provided the alternative service information is fresh (Section 2.2) and the security properties of the alternative service protocol are desirable, as compared to the existing connection.

If a client becomes aware of multiple alternative services, it MAY choose the most suitable according to its own criteria (again, keeping security properties in mind). For example, an origin might advertise multiple alternative services to notify clients of support for multiple versions of HTTP; or, an alternative service might itself advertise an alternative.

A client configured to use a proxy for a given request SHOULD NOT directly connect to an alternative service for it, but instead route it through that proxy.

When a client uses an alternative service for a request, it can indicate this to the server using the Alt-Used header field (Section 5).

The client does not need to block requests on any existing connection; it can be used until the alternative connection is established. However, if the security properties of the existing connection are weak (e.g. cleartext HTTP/1.1) then it might make sense to block until the new connection is fully available in order to avoid information leakage.

Furthermore, if the connection to the alternative service fails or is unresponsive, the client MAY fall back to using the origin or another alternative service. Note, however, that this could be the basis of a downgrade attack, thus losing any enhanced security properties of the alternative service. If the connection to the alternative service does not negotiate the expected protocol (for example, ALPN
fails to negotiate h2, or an Upgrade request to h2c is not accepted), the connection to the alternative service MUST be considered to have failed.

3. The Alt-Svc HTTP Header Field

An HTTP(S) origin server can advertise the availability of alternative services to clients by adding an Alt-Svc header field to responses.

Alt-Svc       = clear / 1#alt-value
clear         = %x63.6C.65.61.72; "clear", case-sensitive
alt-value     = alternative *( OWS ;" ; OWS parameter )
alternative   = protocol-id "=" alt-authority
protocol-id   = token ; percent-encoded ALPN protocol name
alt-authority = quoted-string ; containing [ uri-host ] ";": port
parameter     = token "=" ( token / quoted-string )

The field value consists either of a list of values, each of which indicating one alternative service, or the keyword "clear".

A field value containing the special value "clear" indicates that the origin requests all alternatives for that origin to be invalidated (including those specified in the same response, in case of an invalid reply containing both "clear" and alternative services).

ALPN protocol names are octet sequences with no additional constraints on format. Octets not allowed in tokens ([RFC7230], Section 3.2.6) MUST be percent-encoded as per Section 2.1 of [RFC3986]. Consequently, the octet representing the percent character "%" (hex 25) MUST be percent-encoded as well.

In order to have precisely one way to represent any ALPN protocol name, the following additional constraints apply:

1. Octets in the ALPN protocol name MUST NOT be percent-encoded if they are valid token characters except "%", and
2. When using percent-encoding, uppercase hex digits MUST be used.

With these constraints, recipients can apply simple string comparison to match protocol identifiers.

The "alt-authority" component consists of an OPTIONAL uri-host ("host" in Section 3.2.2 of [RFC3986]), a colon (":"), and a port number.
For example:

```
Alt-Svc: h2=":8000"
```

This indicates the "h2" protocol ([RFC7540]) on the same host using the indicated port 8000.

An example involving a change of host:

```
Alt-Svc: h2="new.example.org:80"
```

This indicates the "h2" protocol on the host "new.example.org", running on port 80. Note that the "quoted-string" syntax needs to be used because ":" is not an allowed character in "token".

Examples for protocol name escaping:

```
+-----------------+--------+---------------------+
| ALPN protocol name | protocol-id | Note                |
+-----------------+--------+---------------------+
| h2              | h2     | No escaping needed  |
+-----------------+--------+---------------------+
| w=x:y#z         | w%3Dx%3Ay#z | "=" and ":" escaped |
+-----------------+--------+---------------------+
| x%y             | x%25y  | "%" needs escaping  |
+-----------------+--------+---------------------+
```

Alt-Svc MAY occur in any HTTP response message, regardless of the status code. Note that recipients of Alt-Svc are free to ignore the header field (and indeed need to in some situations; see Sections 2.1 and 6).

The Alt-Svc field value can have multiple values:

```
Alt-Svc: h2c=":8000", h2=":443"
```

When multiple values are present, the order of the values reflects the server’s preference (with the first value being the most preferred alternative).

The value(s) advertised by Alt-Svc can be used by clients to open a new connection to an alternative service. Subsequent requests can start using this new connection immediately, or can continue using the existing connection while the new connection is created.

When using HTTP/2 ([RFC7540]), servers SHOULD instead send an ALTSVC frame (Section 4). A single ALTSVC frame can be sent for a connection; a new frame is not needed for every request. Note that,
This specification defines two parameters: "ma" and "persist", defined in Section 3.1. Unknown parameters MUST be ignored, that is the values (alt-value) they appear in MUST be processed as if the unknown parameter was not present.

New parameters can be defined in extension specifications (see Section 7.3 for registration details).

Note that all field elements that allow "quoted-string" syntax MUST be processed as per Section 3.2.6 of [RFC7230].

3.1. Caching Alt-Svc Header Field Values

When an alternative service is advertised using Alt-Svc, it is considered fresh for 24 hours from generation of the message. This can be modified with the ‘ma’ (max-age) parameter:

Alt-Svc: h2=":443"; ma=3600

which indicates the number of seconds since the response was generated the alternative service is considered fresh for.

ma = delta-seconds

See Section 4.2.3 of [RFC7234] for details of determining response age.

For example, a response:

HTTP/1.1 200 OK
Content-Type: text/html
Cache-Control: max-age=600
Age: 30
Alt-Svc: h2c=":8000"; ma=60

indicates that an alternative service is available and usable for the next 60 seconds. However, the response has already been cached for 30 seconds (as per the Age header field value), so therefore the alternative service is only fresh for the 30 seconds from when this response was received, minus estimated transit time.

Note that the freshness lifetime for HTTP caching (here, 600 seconds) does not affect caching of Alt-Svc values.

When an Alt-Svc response header field is received from an origin, its
value invalidates and replaces all cached alternative services for that origin.

By default, cached alternative services will be cleared when the client detects a network change. Alternative services that are intended to be longer-lived (e.g., those that are not specific to the client access network) can carry the "persist" parameter with a value "1" as a hint that the service is potentially useful beyond a network configuration change.

\[
\text{persist} = 1\text{DIGIT}
\]

For example:

\[
\text{Alt-Svc: h2=":443"; ma=2592000; persist=1}
\]

This specification only defines a single value for "persist"; others can be defined in future specifications. Clients MUST ignore "persist" parameters with unknown values.

See Section 2.2 for general requirements on caching alternative services.

4. The ALTSVC HTTP/2 Frame

The ALTSVC HTTP/2 frame ([RFC7540], Section 4) advertises the availability of an alternative service to an HTTP/2 client.

The ALTSVC frame is a non-critical extension to HTTP/2. Endpoints that do not support this frame can safely ignore it.

An ALTSVC frame from a server to a client on a stream other than stream 0 indicates that the conveyed alternative service is associated with the origin of that stream.

An ALTSVC frame from a server to a client on stream 0 indicates that the conveyed alternative service is associated with the origin contained in the Origin field of the frame. An association with an origin that the client does not consider authoritative for the current connection MUST be ignored.

The ALTSVC frame type is 0xa (decimal 10).

```
+-------------------------------+-------------------------------+
|         Origin-Len (16)       | Origin? (*)                 ...
+-------------------------------+-------------------------------+
|                   Alt-Svc-Field-Value (*)                   ...
+---------------------------------------------------------------+
```
ALTSVC Frame Payload

The ALTSVC frame contains the following fields:

Origin-Len: An unsigned, 16-bit integer indicating the length, in octets, of the Origin field.

Origin: An OPTIONAL sequence of characters containing the ASCII serialization of an origin ([RFC6454], Section 6.2) that the alternative service is applicable to.

Alt-Svc-Field-Value: A sequence of octets (length determined by subtracting the length of all preceding fields from the frame length) containing a value identical to the Alt-Svc field value defined in Section 3 (ABNF production "Alt-Svc").

The ALTSVC frame does not define any flags.

The ALTSVC frame is intended for receipt by clients; a server that receives an ALTSVC frame can safely ignore it.

An ALTSVC frame on stream 0 with empty (length 0) "Origin" information is invalid and MUST be ignored. An ALTSVC frame on a stream other than stream 0 containing non-empty "Origin" information is invalid and MUST be ignored.

The ALTSVC frame is processed hop-by-hop. An intermediary MUST NOT forward ALTSVC frames, though it can use the information contained in ALTSVC frames in forming new ALTSVC frames to send to its own clients.

5. The Alt-Used HTTP Header Field

The Alt-Used header field is used in requests to indicate the identity of the alternative service in use, just as the Host header field (Section 5.4 of [RFC7230]) identifies the host and port of the origin.

Alt-Used = uri-host [ "": port ]

Alt-Used is intended to allow alternative services to detect loops, differentiate traffic for purposes of load balancing, and generally to ensure that it is possible to identify the intended destination of traffic, since introducing this information after a protocol is in use has proven to be problematic.

When using an alternative service, clients SHOULD include a Alt-Used header field in all requests.
As the Alt-Used header field might be used by the server for tracking the client, a client MAY choose not to include it in its requests for protecting its privacy (see Section 9.4).

For example:

GET /thing HTTP/1.1
Host: origin.example.com
Alt-Used: alternate.example.net

6. The 421 Misdirected Request HTTP Status Code

The 421 (Misdirected Request) status code is defined in Section 9.1.2 of [RFC7540] to indicate that the current server instance is not authoritative for the requested resource. This can be used to indicate that an alternative service is not authoritative; see Section 2).

Clients receiving 421 (Misdirected Request) from an alternative service MUST remove the corresponding entry from its alternative service cache (see Section 2.2) for that origin. Regardless of the idempotency of the request method, they MAY retry the request, either at another alternative server, or at the origin.

An Alt-Svc header field in a 421 (Misdirected Request) response MUST be ignored.

7. IANA Considerations

7.1. Header Field Registrations

HTTP header fields are registered within the "Message Headers" registry maintained at <https://www.iana.org/assignments/message-headers/>.

This document defines the following HTTP header fields, so their associated registry entries shall be added according to the permanent registrations below (see [BCP90]):

<table>
<thead>
<tr>
<th>Header Field Name</th>
<th>Protocol</th>
<th>Status</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-Svc</td>
<td>http</td>
<td>standard</td>
<td>Section 3</td>
</tr>
<tr>
<td>Alt-Used</td>
<td>http</td>
<td>standard</td>
<td>Section 5</td>
</tr>
</tbody>
</table>

The change controller is: "IETF (iesg@ietf.org) - Internet Engineering Task Force".
7.2. The ALTSVC HTTP/2 Frame Type

This document registers the ALTSVC frame type in the HTTP/2 Frame Types registry ([RFC7540], Section 11.2).

Frame Type: ALTSVC
Code: 0xa
Specification: Section 4 of this document

7.3. Alt-Svc Parameter Registry

The HTTP Alt-Svc Parameter Registry defines the name space for the cache directives. It will be created and maintained at (the suggested URI) <http://www.iana.org/assignments/http-alt-svc-parameters>.

7.3.1. Procedure

A registration MUST include the following fields:

- Parameter Name
- Pointer to specification text

Values to be added to this name space require Expert Review (see [RFC5226], Section 4.1).

7.3.2. Registrations

The HTTP Alt-Svc Parameter Registry is to be populated with the registrations below:

<table>
<thead>
<tr>
<th>Alt-Svc Parameter</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>ma</td>
<td>Section 3.1</td>
</tr>
<tr>
<td>persist</td>
<td>Section 3.1</td>
</tr>
</tbody>
</table>

8. Internationalization Considerations

An internationalized domain name that appears in either the header field (Section 3) or the HTTP/2 frame (Section 4) MUST be expressed using A-labels ([RFC5890], Section 2.3.2.1).
9. Security Considerations

9.1. Changing Ports

Using an alternative service implies accessing an origin’s resources on an alternative port, at a minimum. An attacker that can inject alternative services and listen at the advertised port is therefore able to hijack an origin. On certain servers, it is normal for users to be able to control some personal pages available on a shared port, and also to accept requests on less-privileged ports.

For example, an attacker that can add HTTP response header fields to some pages can redirect traffic for an entire origin to a different port on the same host using the Alt-Svc header field; if that port is under the attacker’s control, they can thus masquerade as the HTTP server.

On servers, this risk can be reduced by restricting the ability to advertise alternative services, and restricting who can open a port for listening on that host. Clients can reduce this risk by imposing stronger requirements (e.g. strong authentication) when moving from System Ports to User or Dynamic Ports, or from User Ports to Dynamic Ports, as defined in Section 6 of [RFC6335].

It is always valid for a client to ignore an alternative service advertisement which does not meet its implementation-specific security requirements. Servers can increase the likelihood of clients using the alternative service by providing strong authentication even when not required.

9.2. Changing Hosts

When the host is changed due to the use of an alternative service, it presents an opportunity for attackers to hijack communication to an origin.

For example, if an attacker can convince a user agent to send all traffic for "innocent.example.org" to "evil.example.com" by successfully associating it as an alternative service, they can masquerade as that origin. This can be done locally (see mitigations in Section 9.1) or remotely (e.g., by an intermediary as a man-in-the-middle attack).

This is the reason for the requirement in Section 2.1 that any alternative service with a host different to the origin’s be strongly authenticated with the origin’s identity; i.e., presenting a certificate for the origin proves that the alternative service is authorized to serve traffic for the origin.
However, this authorization is only as strong as the method used to authenticate the alternative service. In particular, there are well-known exploits to make an attacker’s certificate appear as legitimate.

Alternative services could be used to persist such an attack; for example, an intermediary could man-in-the-middle TLS-protected communication to a target, and then direct all traffic to an alternative service with a large freshness lifetime, so that the user agent still directs traffic to the attacker even when not using the intermediary.

Implementations MUST perform any certificate-pinning validation (e.g. [RFC7469]) on alternative services just as they would on direct connections to the origin. Implementations might also choose to add other requirements around which certificates are acceptable for alternative services.

9.3. Changing Protocols

When the ALPN protocol is changed due to the use of an alternative service, the security properties of the new connection to the origin can be different from that of the "normal" connection to the origin, because the protocol identifier itself implies this.

For example, if a "https://" URI has a protocol advertised that does not use some form of end-to-end encryption (most likely, TLS), it violates the expectations for security that the URI scheme implies.

Therefore, clients cannot blindly use alternative services, but instead evaluate the option(s) presented to assure that security requirements and expectations (of specifications, implementations and end users) are met.

9.4. Tracking Clients Using Alternative Services

Choosing an alternative service implies connecting to a new, server-supplied host name. By using many different (potentially unique) host names, servers could conceivably track client requests. Such tracking could follow users across multiple networks, when the "persist" flag is used.

Clients concerned by the additional fingerprinting can choose to ignore alternative service advertisements.

In a user agent, any alternative service information MUST be removed when origin-specific data is cleared (for instance, when cookies are cleared).
9.5. Confusion Regarding Request Scheme

Some server-side HTTP applications make assumptions about security based upon connection context; for example, equating being served upon port 443 with the use of a HTTPS URL (and the various security properties that implies).

This affects not only the security properties of the connection itself, but also the state of the client at the other end of it; for example, a Web browser treats HTTPS URLs differently than HTTP URLs in many ways, not just for purposes of protocol handling.

Since one of the uses of Alternative Services is to allow a connection to be migrated to a different protocol and port, these applications can become confused about the security properties of a given connection, sending information (e.g., cookies, content) that is intended for a secure context (e.g., a HTTPS URL) to a client that is not treating it as one.

This risk can be mitigated in servers by using the URL scheme explicitly carried by the protocol (e.g., ":scheme" in HTTP/2 or the "absolute form" of the request target in HTTP/1.1) as an indication of security context, instead of other connection properties ([RFC7540], Section 8.1.2.3 and [RFC7230], Section 5.3.2).

When the protocol does not explicitly carry the scheme (e.g., as is usually the case for HTTP/1.1 over TLS, servers can, mitigate this risk by either assuming that all requests have an insecure context, or by refraining from advertising alternative services for insecure schemes (such as HTTP).

Internet-Draft          HTTP Alternative Services          November 2015

RFC5246, August 2008,

Appendix A. Change Log (to be removed by RFC Editor before publication)

A.1. Since draft-nottingham-httpbis-alt-svc-05

This is the first version after adoption of draft-nottingham-httpbis-alt-svc-05 as Working Group work item. It only contains editorial changes.

A.2. Since draft-ietf-httpbis-alt-svc-00

Selected 421 as proposed status code for "Not Authoritative".

Changed header field syntax to use percent-encoding of ALPN protocol names (<https://github.com/http2/http2-spec/issues/446>).

A.3. Since draft-ietf-httpbis-alt-svc-01

Updated HTTP/1.1 references.

Renamed "Service" to "Alt-Svc-Used" and reduced information to a flag to address fingerprinting concerns (<https://github.com/http2/http2-spec/issues/502>).

Note that ALTSVC frame is preferred to Alt-Svc header field (<https://github.com/http2/http2-spec/pull/503>).

Moved definition of status code 421 to HTTP/2.

A.4. Since draft-ietf-httpbis-alt-svc-02

Updated ALPN reference.

A.5. Since draft-ietf-httpbis-alt-svc-03

Renamed "Alt-Svc-Used" to "Alt-Used"

Clarify ALTSVC Origin information requirements

Remove/tune language with respect to tracking risks (see

Mention tracking by alt-svc host name in Security Considerations

"421 (Not Authoritative)" -> "421 (Misdirected Request)".

Allow the frame to carry multiple indicator and use the same payload
formats for both

A.7. Since draft-ietf-httpbis-alt-svc-05

Go back to specifying the origin in Alt-Used, but make it a "SHOULD"

Restore Origin field in ALT-SVC frame

A.8. Since draft-ietf-httpbis-alt-svc-06

Disallow use of alternative services when the protocol might not
carry the scheme

Align opp-sec and alt-svc

alt svc frame on pushed (even and non-0) frame
"browser" -> "user agent"

ABNF for "parameter"

Updated HTTP/2 reference.

A.9. Since draft-ietf-httpbis-alt-svc-07

Alt-Svc alternative cache invalidation

Unexpected Alt-Svc frames

Associating Alt-Svc header with an origin

ALPN identifiers in Alt-Svc
(http://github.com/httpwg/http-extensions/issues/43).

Number of alternate services used

Proxy and .pac interaction

Need to define extensibility for alt-svc parameters

Persistence of alternates across network changes

Alt-Svc header with 421 status
(http://github.com/httpwg/http-extensions/issues/75).

Incorporate several editorial improvements suggested by Mike Bishop
(http://github.com/httpwg/http-extensions/pull/77,

Alt-Svc response header field in HTTP/2 frame

A.10. Since draft-ietf-httpbis-alt-svc-08

Remove left over text about ext-params, applying to an earlier
version of Alt-Used (see
Conflicts between Alt-Svc and ALPN

Elevation of privilege

Alternates of alternates

Alt-Svc and Cert Pinning

Using alt-svc on localhost (no change to spec, see

IANA procedure for alt-svc parameters

Alt-svc from https (1.1) to https (1.1)

Alt-svc vs the ability to convey the scheme inside the protocol

Reconciling MAY/can vs. SHOULD

Typo in alt-svc caching example

Appendix B. Acknowledgements

Thanks to Adam Langley, Bence Beky, Eliot Lear, Erik Nygren, Guy Podjarny, Herve Ruellan, Martin Thomson, Matthew Kerwin, Mike Bishop, Paul Hoffman, Richard Barnes, Richard Bradbury, Stephen Farrell, Stephen Ludin, and Will Chan for their feedback and suggestions.

The Alt-Svc header field was influenced by the design of the Alternate-Protocol header field in SPDY.

Hypertext Transfer Protocol (HTTP) Client-Initiated Content-Encoding
draft-ietf-httpbis-cice-03

Abstract

In HTTP, content codings allow for payload encodings such as for compression or integrity checks. In particular, the "gzip" content coding is widely used for payload data sent in response messages.

Content codings can be used in request messages as well, however discoverability is not on par with response messages. This document extends the HTTP "Accept-Encoding" header field for use in responses, to indicate the content codings that are supported in requests.

Editorial Note (To be removed by RFC Editor before publication)

Discussion of this draft takes place on the HTTPBIS working group mailing list (ietf-http-wg@w3.org), which is archived at <https://lists.w3.org/Archives/Public/ietf-http-wg/>.

Working Group information can be found at <https://tools.ietf.org/wg/httpbis/> and <http://httpwg.github.io/>; source code and issues list for this draft can be found at <https://github.com/httpwg/http-extensions>.

The changes in this draft are summarized in Appendix A.6.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."
1. Introduction

In HTTP, content codings allow for payload encodings such as for compression or integrity checks ([RFC7231], Section 3.1.2). In particular, the "gzip" content coding ([RFC7230], Section 4.2) is widely used for payload data sent in response messages.

Content codings can be used in request messages as well, however discoverability is not on par with response messages. This document extends the HTTP "Accept-Encoding" header field ([RFC7231], Section 5.3.4) for use in responses, to indicate the content codings that are supported in requests. It furthermore updates the definition of status code 415 (Unsupported Media Type) ([RFC7231], Section 6.5.13), recommending to include the "Accept-Encoding" header field when appropriate.

2. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This document reuses terminology defined in the base HTTP specifications, namely Section 2 of [RFC7230] and Section 3.1.2 of [RFC7231].

3. Using the 'Accept-Encoding' Header Field in Responses

Section 5.3.4 of [RFC7231] defines "Accept-Encoding" as a request header field only.

This specification expands that definition to allow "Accept-Encoding" as a response header field as well. When present in a response, it indicates what content codings the resource was willing to accept in the associated request. A field value that only contains "identity" implies that no content codings were supported.

Note that this information is specific to the associated request; the set of supported encodings might be different for other resources on the same server, and could change over time or depend on other aspects of the request (such as the request method).

Section 6.5.13 of [RFC7231] defines status code 415 (Unsupported Media Type) to apply to both media type and content coding related problems.

Servers that fail a request due to an unsupported content coding ought to respond with a 415 status and ought to include an "Accept-
Encoding" header field in that response, allowing clients to
distinguish between content coding related issues and media type
related issues. In order to avoid confusion with media type related
problems, servers that fail a request with a 415 status for reasons
unrelated to content codings MUST NOT include the "Accept-Encoding"
header field.

It is expected that the most common use of "Accept-Encoding" in
responses will have the 415 (Unsupported Media Type) status code, in
response to optimistic use of a content coding by clients. However,
the header field can also be used to indicate to clients that content
codings are supported, to optimize future interactions. For example,
a resource might include it in a 2xx response when the request
payload was big enough to justify use of a compression coding, but
the client failed do so.

4. Example

A client submits a POST request using the "compress" content coding
([RFC7231], Section 3.1.2.1):

    POST /edit/ HTTP/1.1
    Host: example.org
    Content-Type: application/atom+xml;type=entry
    Content-Encoding: compress

    ...compressed payload...

The server rejects request because it only allows the "gzip" content
coding:

    HTTP/1.1 415 Unsupported Media Type
    Date: Fri, 09 May 2014 11:43:53 GMT
    Accept-Encoding: gzip
    Content-Length: 68
    Content-Type: text/plain

This resource only supports the "gzip" content coding in requests.

...at which point the client can retry the request with the supported
"gzip" content coding.

Alternatively, a server that does not support any content codings in
requests could answer with:
HTTP/1.1 415 Unsupported Media Type
Date: Fri, 09 May 2014 11:43:53 GMT
Accept-Encoding: identity
Content-Length: 61
Content-Type: text/plain

This resource does not support content codings in requests.

5. Deployment Considerations

Servers that do not support content codings in requests already are required to fail a request that uses a content coding. Section 6.5.13 of [RFC7231] defines the status code 415 (Unsupported Media Type) for this purpose, so the only change needed is to include the "Accept-Encoding" header field with value "identity" in that response.

Servers that do support some content codings are required to fail requests with unsupported content codings as well. To be compliant with this specification, servers will need to use the status code 415 (Unsupported Media Type) to signal the problem, and will have to include an "Accept-Encoding" header field that enumerates the content codings that are supported. As the set of supported content codings is usually static and small, adding the header field ought to be trivial.

6. Security Considerations

This specification only adds discovery of supported content codings and diagnostics for requests failing due to unsupported content codings. As such, it doesn’t introduce any new security considerations over those already present in HTTP/1.1 (Section 9 of [RFC7231]) and HTTP/2 (Section 10 of [RFC7540]).

However, the point of better discoverability and diagnostics is to make it easier to use content codings in requests. This might lead to increased usage of compression codings such as gzip (Section 4.2 of [RFC7230]), which, when used over a secure channel, can enable side-channel attacks such as BREACH (see Section 10.6 of [RFC7540] and [BREACH]). At the time of publication, it was unclear how BREACH-like attacks can be applied to compression in HTTP requests.

7. IANA Considerations

7.1. Header Field Registry

HTTP header fields are registered within the "Message Headers" registry located at
<http://www.iana.org/assignments/message-headers>, as defined by [BCP90].

This document updates the definition of the "Accept-Encoding" header field, so the "Permanent Message Header Field Names" registry ought to be updated accordingly:

<table>
<thead>
<tr>
<th>Header Field Name</th>
<th>Protocol</th>
<th>Status</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept-Encoding</td>
<td>http</td>
<td>standard</td>
<td>[RFC7231], Section 5.3.4, and Section 3 of this document</td>
</tr>
</tbody>
</table>

7.2. Status Code Registry

HTTP status codes are registered within the "Status Code" registry located at <http://www.iana.org/assignments/http-status-codes>.

This document updates the definition of the status code 415 (Unsupported Media Type), so the "Status Code" registry ought to be updated accordingly:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>415</td>
<td>Unsupported Media Type</td>
<td>[RFC7231], Section 6.5.13, and Section 3 of this document</td>
</tr>
</tbody>
</table>

8. References

8.1. Normative References

8.2.  Informative References

Appendix A.  Change Log (to be removed by RFC Editor before publication)

A.1.  Since draft-reschke-http-cice-00
  Clarified that the information returned in Accept-Encoding is per resource, not per server.
  Added some deployment considerations.
  Updated HTTP/1.1 references.

A.2.  Since draft-reschke-http-cice-01
  Restrict the scope of A-E from "future requests" to "at the time of this request".
  Mention use of A-E in responses other than 415.
  Recommend not to include A-E in a 415 response unless there was actually a problem related to content coding.

A.3.  Since draft-reschke-http-cice-02
  First Working Group draft; updated boilerplate accordingly.

A.4.  Since draft-ietf-httpbis-cice-00
  Apply editorial improvements suggested by Mark Nottingham.
A.5. Since draft-ietf-httpbis-cice-01

Clarify that we’re also extending the definition of status code 415 (so update that IANA registry entry as well).

A.6. Since draft-ietf-httpbis-cice-02

Removed normative language that required used of Accept-Encoding in responses (which would have made existing servers non-compliant).

# 1. Introduction

This document describes a use of HTTP Alternative Services [I-D.ietf-httpbis-alt-svc] to decouple the URI scheme from the use and configuration of underlying encryption, allowing a "http" URI to be accessed using TLS [RFC5246] opportunistically.

Serving "https" URIs require acquiring and configuring a valid certificate, which means that some deployments find supporting TLS difficult. This document describes a usage model whereby sites can serve "http" URIs over TLS without being required to support strong server authentication.

Opportunistic Security [RFC7435] does not provide the same guarantees as using TLS with "https" URIs; it is vulnerable to active attacks, and does not change the security context of the connection. Normally, users will not be able to tell that it is in use (i.e., there will be no "lock icon").

By its nature, this technique is vulnerable to active attacks. A mechanism for partially mitigating them is described in Section 5.
1.1. Goals and Non-Goals

The immediate goal is to make the use of HTTP more robust in the face of pervasive passive monitoring [RFC7258].

A secondary goal is to limit the potential for active attacks. It is not intended to offer the same level of protection as afforded to "https" URIs, but instead to increase the likelihood that an active attack can be detected.

A final (but significant) goal is to provide for ease of implementation, deployment and operation. This mechanism is expected to have a minimal impact upon performance, and a trivial administrative effort to configure.

1.2. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

2. Using HTTP URIs over TLS

An origin server that supports the resolution of "http" URIs can indicate support for this specification by providing an alternative service advertisement [I-D.ietf-httpbis-alt-svc] for a protocol identifier that uses TLS, such as "h2" [RFC7540].

A client that receives such an advertisement MAY make future requests intended for the associated origin ([RFC6454]) to the identified service (as specified by [I-D.ietf-httpbis-alt-svc]).

A client that places the importance of protection against passive attacks over performance might choose to withhold requests until an encrypted connection is available. However, if such a connection cannot be successfully established, the client can resume its use of the cleartext connection.

A client can also explicitly probe for an alternative service advertisement by sending a request that bears little or no sensitive information, such as one with the OPTIONS method. Likewise, clients with existing alternative services information could make such a request before they expire, in order minimize the delays that might be incurred.
3. Server Authentication

By their nature, "http" URIs do not require cryptographically strong server authentication; that is only implied by "https" URIs. Furthermore, doing so (as per [RFC2818]) creates a number of operational challenges. For these reasons, server authentication is not mandatory for "http" URIs when using the mechanism described in this specification.

When connecting to an alternative service for an "http" URI, clients are not required to perform the server authentication procedure described in Section 3.1 of [RFC2818]. The server certificate, if one is proffered by the alternative service, is not necessarily checked for validity, expiration, issuance by a trusted certificate authority or matched against the name in the URI. Therefore, the alternative service can provide any certificate, or even select TLS cipher suites that do not include authentication.

A client MAY perform additional checks on the offered certificate if the server does not select an unauthenticated TLS cipher suite. This document doesn’t define any such checks, though clients could be configured with a policy that defines what is acceptable.

As stipulated by [I-D.ietf-httpbis-alt-svc], clients MUST NOT use alternative services with a host other than the origin’s, unless the alternative service itself is strongly authenticated (as the origin’s host); for example, using TLS with a certificate that validates as per [RFC2818].

4. Interaction with "https" URIs

When using alternative services, requests for resources identified by both "http" and "https" URIs might use the same connection, because HTTP/2 permits requests for multiple origins on the same connection.

Since "https" URIs rely on server authentication, a connection that is initially created for "http" URIs without authenticating the server cannot be used for "https" URIs until the server certificate is successfully authenticated. Section 3.1 of [RFC2818] describes the basic mechanism, though the authentication considerations in [I-D.ietf-httpbis-alt-svc] also apply.

Connections that are established without any means of server authentication (for instance, the purely anonymous TLS cipher suites), cannot be used for "https" URIs.
5. Requiring Use of TLS

Editors’ Note: this is a very rough take on an approach that would provide a limited form of protection against downgrade attack. It’s unclear at this point whether the additional effort (and modest operational cost) is worthwhile.

The mechanism described in this specification is trivial to mount an active attack against, for two reasons:

- A client that doesn’t perform authentication is an easy victim of server impersonation, through man-in-the-middle attacks.
- A client that is willing to use HTTP over cleartext to resolve the resource will do so if access to any TLS-enabled alternative services is blocked at the network layer.

Given that the primary goal of this specification is to prevent passive attacks, these are not critical failings (especially considering the alternative - HTTP over cleartext). However, a modest form of protection against active attacks can be provided for clients on subsequent connections.

When an alternative service is able to commit to providing service for a particular origin over TLS for a bounded period of time, clients can choose to rely upon its availability, failing when it cannot be contacted. Effectively, this makes the choice to use a secured protocol "sticky" in the client.

5.1. The HTTP-TLS Header Field

A alternative service can make this commitment by sending a "HTTP-TLS" header field, described here using the ‘#’ ABNF extension defined in Section 7 of [RFC7230]:

```
HTTP-TLS = 1#parameter
```

When it appears in a HTTP response from a strongly authenticated alternative service, this header field indicates that the availability of the origin through TLS-protected alternative services is "sticky", and that the client MUST NOT fall back to cleartext protocols while this information is considered fresh.

For example:
GET /index.html HTTP/1.1
Host: example.com

HTTP/1.1 200 OK
Content-Type: text/html
Cache-Control: max-age=600
Age: 30
Date: Thu, 1 May 2014 16:20:09 GMT
HTTP-TLS: ma=3600

This header field creates a commitment from the origin [RFC6454] of the associated resource (in the example, "http://example.com"). For the duration of the commitment, clients SHOULD strongly authenticate the server for all subsequent requests made to that origin, though this creates some risks for clients (see Section 5.2).

Authentication for HTTP over TLS is described in Section 3.1 of [RFC2818], noting the additional requirements in Section 2.1 of [I-D.ietf-httpbis-alt-svc]. The header field MUST be ignored if strong authentication fails; otherwise, an attacker could create a persistent denial of service by falsifying a commitment.

The commitment to use authenticated TLS persists for a period determined by the value of the "ma" parameter. See Section 4.2.3 of [RFC7234] for details of determining response age.

ma-parameter = delta-seconds

The commitment made by the "HTTP-TLS" header field applies only to the origin of the resource that generates the "HTTP-TLS" header field.

Requests for an origin that has a persisted, unexpired value for "HTTP-TLS" MUST fail if they cannot be made over an authenticated TLS connection.

Note that the commitment is not bound to a particular alternative service. Clients SHOULD use alternative services that they become aware of. However, clients MUST NOT use an unauthenticated alternative service for an origin with this commitment. Where there is an active commitment, clients MAY instead ignore advertisements for unsecured alternatives services.
5.2. Operational Considerations

To avoid situations where a persisted value of "HTTP-TLS" causes a client to be unable to contact a site, clients SHOULD limit the time that a value is persisted for a given origin. A lower limit might be appropriate for initial observations of "HTTP-TLS"; the certainty that a site has set a correct value - and the corresponding limit on persistence - can increase as the value is seen more over time.

Once a server has indicated that it will support authenticated TLS, a client MAY use key pinning [RFC7469] or any other mechanism that would otherwise be restricted to use with "https" URIs, provided that the mechanism can be restricted to a single HTTP origin.

6. Security Considerations

6.1. Security Indicators

User Agents MUST NOT provide any special security indicia when an "http" resource is acquired using TLS. In particular, indicators that might suggest the same level of security as "https" MUST NOT be used (e.g., using a "lock device").

6.2. Downgrade Attacks

A downgrade attack against the negotiation for TLS is possible. With the "HTTP-TLS" header field, this is limited to occasions where clients have no prior information (see Section 6.3), or when persisted commitments have expired.

For example, because the "Alt-Svc" header field [I-D.ietf-httpbis-alt-svc] likely appears in an unauthenticated and unencrypted channel, it is subject to downgrade by network attackers. In its simplest form, an attacker that wants the connection to remain in the clear need only strip the "Alt-Svc" header field from responses.

Downgrade attacks can be partially mitigated using the "HTTP-TLS" header field, because when it is used, a client can avoid using cleartext to contact a supporting server. However, this only works when a previous connection has been established without an active attacker present; a continuously present active attacker can either prevent the client from ever using TLS, or offer its own certificate.
6.3. Privacy Considerations

Cached alternative services can be used to track clients over time; e.g., using a user-specific hostname. Clearing the cache reduces the ability of servers to track clients; therefore clients MUST clear cached alternative service information when clearing other origin-based state (i.e., cookies).

6.4. Confusion Regarding Request Scheme

Many existing HTTP/1.1 implementations use the presence or absence of TLS in the stack to determine whether requests are for "http" or "https" resources. This is necessary in many cases because the most common form of an HTTP/1.1 request does not carry an explicit indication of the URI scheme.

HTTP/1.1 MUST NOT be used for opportunistically secured requests.

The Key HTTP Response Header Field
draft-ietf-httpbis-key-00

Abstract

The ‘Key’ header field for HTTP responses allows an origin server to
describe the secondary cache key ([RFC7234], section 4.1) for a
resource, by conveying what is effectively a short algorithm that can
be used upon later requests to determine if a stored response is
reusable for a given request.

Key has the advantage of avoiding an additional round trip for
validation whenever a new request differs slightly, but not
significantly, from prior requests.

Key also informs user agents of the request characteristics that
might result in different content, which can be useful if the user
agent is not sending request header fields in order to reduce the
risk of fingerprinting.

Note to Readers

The issues list for this draft can be found at

Status of This Memo

This Internet-Draft is submitted in full conformance with the
provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering
Task Force (IETF). Note that other groups may also distribute
working documents as Internet-Drafts. The list of current Internet-
Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months
and may be updated, replaced, or obsoleted by other documents at any
time. It is inappropriate to use Internet-Drafts as reference
material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 21, 2016.
1. Introduction

In HTTP caching [RFC7234], the Vary response header field effectively modifies the key used to store and access a response to include information from the request’s headers. This "secondary cache key" allows proactive content negotiation [RFC7231] to work with caches.
Vary’s operation is generic; it works well when caches understand the semantics of the selecting headers. For example, the Accept-Language request header field has a well-defined syntax for expressing the client’s preferences; a cache that understands this header field can select the appropriate response (based upon its Content-Language header field) and serve it to a client, without any knowledge of the underlying resource.

Vary does not work as well when the criteria for selecting a response are specific to the resource. For example, if the nature of the response depends upon the presence or absence of a particular Cookie ([RFC6265]) in a request, Vary doesn’t have a mechanism to offer enough fine-grained, resource-specific information to aid a cache’s selection of the appropriate response.

This document defines a new response header field, "Key", that allows resources to describe the secondary cache key in a fine-grained, resource-specific manner, leading to improved cache efficiency when responses depend upon such headers.

1.1. Examples

For example, this response header field:

   Key: cookie;param=_sess;param=ID

indicates that the selected response depends upon the "_sess" and "ID" cookie values.

This Key:

   Key: user-agent;substr=MSIE

indicates that there are two possible secondary cache keys for this resource; one for requests whose User-Agent header field contains "MSIE", and another for those that don’t.

A more complex example:

   Key: user-agent;substr=MSIE;Substr="mobile", Cookie;param=ID

indicates that the selected response depends on the presence of two strings in the User-Agent request header field, as well as the value of the "ID" cookie request header field.
1.2. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This document uses the Augmented Backus-Naur Form (ABNF) notation of [RFC5234] (including the DQUOTE rule), and the list rule extension defined in [RFC7230], Section 7. It includes by reference the field-name, quoted-string and quoted-pair rules from that document, and the parameter rule from [RFC7231].

2. The "Key" Response Header Field

The "Key" response header field describes the portions of the request that the resource currently uses to select representations.

As such, its semantics are similar to the "Vary" response header field, but it allows more fine-grained description, using "key parameters".

Caches can use this information as part of determining whether a stored response can be used to satisfy a given request. When a cache knows and fully understands the Key header field for a given resource, it MAY ignore the Vary response header field in any stored responses for it.

Additionally, user agents can use Key to discover if additional request header fields might influence the resource’s selection of responses.

The Key field-value is a comma-delimited list of selecting header fields (similar to Vary), with zero to many parameters each, delimited by semicolons. Whitespace is not allowed in the field-value between each field-name and its parameter set.

Key = 1#field-name *( ";" parameter )

Note that, as per [RFC7231], parameter names are case-insensitive, and parameter values can be double-quoted strings (potentially with "\"-escaped characters inside).

The following header fields have the same effect:

Vary: Accept-Encoding, Cookie
Key: Accept-Encoding, Cookie
However, Key’s use of parameters allows:

Key: Accept-Encoding, Cookie;param=foo

to indicate that the secondary cache key depends upon the Accept-Encoding header field and the "foo" Cookie.

One important difference between Vary and Key is how they are applied. Vary is specified to be specific to the response it occurs within, whereas Key is specific to the resource (as identified by the request URL) it is associated with. The most recent key you receive for a given resource is applicable to all responses from that resource.

This difference allows more efficient implementation (and reflects practices that many caches use in implementing Vary already).

This specification defines a selection of Key parameters to address common use cases such as selection upon individual Cookie header fields, User-Agent substrings and numerical ranges. Future parameters may define further capabilities.

2.1. Relationship with Vary

Origin servers SHOULD still send Vary when using Key, to ensure backwards compatibility.

For example,

Vary: User-Agent
Key: User-Agent; substr="mozilla"

Note that, in some cases, it may be better to explicitly use "Vary: *" if clients and caches don’t have any practical way to use the Vary header field’s value. For example,

Vary: *
Key: Cookie; param="ID"

Except when Vary: * is used, the set of headers used in Key SHOULD reflect the same request header fields as Vary does, even if they don’t have parameters. For example,
Here, Accept-Encoding is included in Key without parameters; caches MAY treat these as they do values in the Vary header, relying upon knowledge of their generic semantics to select an appropriate response.

2.2. Calculating a Secondary Cache Key

When used by a cache to determine whether a stored response can be used to satisfy a presented request, each field-name in Key identifies a potential request header, just as with the Vary response header field.

However, each of these can have zero to many key parameters that change how the response selection process (as defined in [RFC7234], Section 4.3) works.

In particular, when a cache fully implements this specification, it creates a secondary cache key for every request by following the instructions in the Key header field, ignoring the Vary header for this purpose.

Then, when a new request is presented, the secondary cache key generated for that request can be compared to the stored one to find the appropriate response, to determine if it can be selected.

To generate a secondary cache key for a given request (including that which is stored with a response) using Key, the following steps are taken:

1) If the Key header field is not present on the most recent cacheable (as per [RFC7234], Section 3) response seen for the resource, abort this algorithm (i.e., fall back to using Vary to determine the secondary cache key).
2) Let "key_value" be the most recently seen Key header field value for the resource, as the result of Creating a Header Field Value (Section 2.2.1).
3) Let "secondary_key" be an empty string.
4) Create "key_list" by splitting "key_value" on "," characters.
5) For "key_item" in "key_list":
   1) Remove any leading and trailing WSP from "key_item".
   2) If "key_item" does not contain a ";" character, fail parameter processing (Section 2.2.2) and skip to the next "key_item".
3) Let "field_name" be the string before the first ";" character in "key_item".
4) Let "field_value" be the result of Creating a Header Field Value (Section 2.2.1) with "field_name" as the "target_field_name" and the request header list as "header_list".
5) Let "parameters" be the string after the first ";" character in "key_item".
6) Create "param_list" by splitting "parameters" on ";" characters, excepting ";" characters within quoted strings, as per [RFC7230] Section 3.2.6.
7) For "parameter" in "param_list":
   1) If "parameter" does not contain a "="", fail parameter processing (Section 2.2.2) and skip to the next "key_item".
   2) Let "param_name" be the string before the first "=" character in "parameter", case-normalized to lowercase.
   3) If "param_name" does not identify a Key parameter processing algorithm that is implemented, fail parameter processing (Section 2.2.2) and skip to the next "key_item".
   4) Let "param_value" be the string after the first "=" character in "parameter".
   5) If the first and last characters of "param_value" are both DQUOTE:
      1) Remove the first and last characters of "param_value".
      2) Replace quoted-pairs within "param_value" with the octet following the backslash, as per [RFC7230] Section 3.2.6.
   6) If "param_value" does not conform to the syntax defined for it by the parameter definition, fail parameter processing Section 2.2.2 and skip to the next "key_item".
   7) Run the identified processing algorithm on "field_value" with the "param_value", and append the result to "secondary_key". If parameter processing fails Section 2.2.2, skip to the next "key_item".
   8) Append a separator character (e.g., NULL) to "secondary_key".
6) Return "secondary_key".

Note that this specification does not require that exact algorithm to be implemented. However, implementations’ observable behavior MUST be identical to running it. This includes parameter processing algorithms; implementations MAY use different internal artefacts for secondary cache keys, as long as the results are the same.
Likewise, while the secondary cache key associated with both stored
and presented requests is required to use the most recently seen Key
header field for the resource in question, this can be achieved using
a variety of implementation strategies, including (but not limited
to):

- Generating a new secondary cache key for every stored response
  associated with the resource upon each request.
- Caching the secondary cache key with the stored request/response
  pair and re-generating it when the Key header field is observed to
  change.
- Caching the secondary cache key with the stored response and
  invalidating the stored response(s) when the Key header field is
  observed to change.

2.2.1. Creating a Header Field Value

Given a header field name "target_field_name" and "header_list", a
list of ("field_name", "field_value") tuples:

1) Let "target_field_values" be an empty list.
2) For each ("field_name", "field_value") tuple in "header_list":
   1) If "field_name" does not match "target_field_name", skip to
      the next tuple.
   2) Strip leading and trailing WSP from "field_value" and append
      it to "target_field_values".
   3) If "target_field_values" is empty, return an empty string.
   4) Return the concatenation of "target_field_values", separating
      each with "," characters.

2.2.2. Failing Parameter Processing

In some cases, a key parameter cannot determine a secondary cache key
 corresponding to its nominated header field value. When this
 happens, Key processing needs to fail safely, so that the correct
 behavior is observed.

When this happens, implementations MUST either behave as if the Key
 header was not present, or assure that the nominated header fields
 being compared match, as per [RFC7234], Section 4.1.

2.3. Key Parameters

A Key parameter associates a name with a specific processing
 algorithm that takes two inputs; a HTTP header value "header_value"
 (as described in Section 2.2.1), and "parameter_value", a string that
 indicates how the identified header should be processed.
The set of key parameters (and their associated processing algorithms) is extensible; see Section 3. This document defines the following key parameters:

2.3.1. div

The "div" parameter normalizes positive integer header values into groups by dividing them by a configured value.

Its value’s syntax is:

div = 1*DIGIT

To process a set of header fields against a div parameter, follow these steps (or their equivalent):

1) If "parameter_value" is "0", fail parameter processing Section 2.2.2.
2) If "header_value" is the empty string, return "none".
3) If "header_value" contains a ",", remove it and all subsequent characters.
4) Remove all WSP characters from "header_value".
5) If "header_value" does not match the div ABNF rule, fail parameter processing (Section 2.2.2).
6) Return the quotient of "header_value" / "parameter_value" (omitting the modulus).

For example, the Key:

Key: Bar;div=5

indicates that the "Bar" header’s field value should be partitioned into groups of 5. Thus, the following field values would be considered the same (because, divided by 5, they all result in 1):

Bar: 1
Bar: 3 , 42
Bar: 4, 1

whereas these would be considered to be in a different group (because, divided by 5, they all result in 2);
2.3.2. partition

The "partition" parameter normalizes positive numeric header values into pre-defined segments.

Its value’s syntax is:

\[
\text{partition} = [ \text{segment} ] * ( ":" [ \text{segment} ] ) \\
\text{segment} = [ 0^*\text{DIGIT } \"\." ] 1^*\text{DIGIT}
\]

To process a set of header fields against a partition parameter, follow these steps (or their equivalent):

1) If "header_value" is the empty string, return "none".
2) If "header_value" contains a ",", remove it and all subsequent characters.
3) Remove all WSP characters from "header_value".
4) If "header_value" does not match the segment ABNF rule, fail parameter processing (Section 2.2.2).
5) Let "segment_id" be 0.
6) Create a list "segment_list" by splitting "parameter_value" on "\:" characters.
7) For each "segment_value" in "segment_list":

   1) If "header_value" is less than "segment_value" when they are numerically compared, skip to step 7.
   2) Increment "segment_id" by 1.
8) Return "segment_id".

For example, the Key:

Key: Foo;partition=20:30:40

indicates that the "Foo" header’s field value should be divided into four segments:

- less than 20
- 20 to less than 30
- 30 to less than 40
- forty or greater
Thus, the following headers would all be normalized to the first segment:

```
Foo: 1
Foo: 0
Foo: 4, 54
Foo: 19.9
```

whereas the following would fall into the second segment:

```
Foo: 20
Foo: 29.999
Foo: 24, 10
```

2.3.3. match

The "match" parameter is used to determine if an exact value occurs in a list of header values. It is case-sensitive.

Its value’s syntax is:

```
match  = ( token / quoted-string )
```

To process a set of header fields against a match parameter, follow these steps (or their equivalent):

1) If "header_value" is the empty string, return "none".
2) Create "header_list" by splitting "header_value" on "," characters.
3) For each "header_item" in "header_list":
   1) Remove leading and trailing WSP characters in "header_item".
   2) If the value of "header_item" is character-for-character identical to "parameter_value", return "1".
4) Return "0".

For example, the Key:

```
Key: Baz;match="charlie"
```

Would return "1" for the following header field values:
Baz: charlie
Baz: foo, charlie
Baz: bar, charlie     , abc

and "0" for these:

Baz: theodore
Baz: joe, sam
Baz: "charlie"
Baz: Charlie
Baz: cha rlie
Baz: charlie2

2.3.4. substr

The "substr" parameter is used to determine if a value occurs as a substring of an item in a list of header values. It is case-sensitive.

Its value’s syntax is:

substr  = ( token / quoted-string )

To process a set of header fields against a substr parameter, follow these steps (or their equivalent):

1) If "header_value" is the empty string, return "none".
2) Create "header_list" by splitting "header_value" on "," characters.
3) For each "header_item" in "header_list":
   1) Remove leading and trailing WSP characters in "header_item".
   2) If the value of "parameter_value" is character-for-character present as a substring of "header_value", return "1".
4) Return "0".

For example, the Key:

Key: Abc;substr=bennet

Would return "1" for the following header field values:
Abc: bennet
Abc: foo, bennet
Abc: abennet00
Abc: bar, 99bennet   , abc
Abc: "bennet"

and "0" for these:

Abc: theodore
Abc: joe, sam
Abc: Bennet
Abc: Ben net

2.3.5. param

The "param" parameter considers the request header field as a list of
key=value parameters, and uses the nominated key’s value as the
secondary cache key.

Its value’s syntax is:

\[
\text{param} = ( \text{token} / \text{quoted-string} )
\]

To process a list of header fields against a param parameter, follow
these steps (or their equivalent):

1) Let "header_list" be an empty list.
2) Create "header_list_tmp1" by splitting header_value on "," characters.
3) For each "header_item_tmp1" in "header_list_tmp1":
   1) Create "header_list_tmp2" by splitting "header_item_tmp1" on ";" characters.
   2) For each "header_item_tmp2" in "header_list_tmp2":
      1) Remove leading and trailing WSP from "header_item_tmp2".
      2) Append "header_item_tmp2" to header_list.
   4) For each "header_item" in "header_list":
      1) If the "=" character does not occur within "header_item",
         skip to the next "header_item".
      2) Let "item_name" be the string occurring before the first "="
         character in "header_item".
      3) If "item_name" does not case-insensitively match
         "parameter_value", skip to the next "header_item".
4) Return the string occurring after the first "=" character in "header_item".
5) Return the empty string.

Note that steps 2 and 3 accommodate semicolon-separated values, so that it can be used with the Cookie request header field.

For example, the Key:

Key: Def;param=liam

The following headers would return the string (surrounded in single quotes) indicated:

```
Def: liam=123  // '123'
Def: mno=456   // ''
Def:            // ''
Def: abc=123; liam=890  // '890'
Def: liam="678"   // '"678"'
```

3. IANA Considerations

This specification defines the HTTP Key Parameter Registry, maintained at http://www.iana.org/assignments/http-parameters/http-parameters.xhtml#key.

3.1. Procedure

Key Parameter registrations MUST include the following fields:

- Parameter Name: [name]
- Reference: [Pointer to specification text]

Values to be added to this namespace require IETF Review (see Section 4.1 of [RFC5226]) and MUST conform to the purpose of content coding defined in this section.

3.2. Registrations

This specification makes the following entries in the HTTP Key Parameter Registry:
4. Security Considerations

Because Key is an alternative to Vary, it is possible for caches to behave differently based upon whether they implement Key. Likewise, because support for any one Key parameter is not required, it is possible for different implementations of Key to behave differently. In both cases, an attacker might be able to exploit these differences.

This risk is mitigated by the requirement to fall back to Vary when unsupported parameters are encountered, coupled with the requirement that servers that use Key also include a relevant Vary header.

An attacker with the ability to inject response headers might be able to perform a cache poisoning attack that tailors a response to a specific user (e.g., by Keying to a Cookie that’s specific to them). While the attack is still possible without Key, the ability to tailor is new.

When implemented, Key might result in a larger number of stored responses for a given resource in caches; this, in turn, might be used to create an attack upon the cache itself. Good cache replacement algorithms and denial of service monitoring in cache implementations are reasonable mitigations against this risk.

An HTTP Status Code to Report Legal Obstacles
draft-ietf-httpbis-legally-restricted-status-04

Abstract

This document specifies a Hypertext Transfer Protocol (HTTP) status code for use when resource access is denied as a consequence of legal demands.

Editorial Note (To be removed by RFC Editor before publication)

Discussion of this draft takes place on the HTTPBIS working group mailing list (ietf-http-wg@w3.org), which is archived at [1].

Working Group information can be found at [2] and [3]; source code and issues list for this draft can be found at [4].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 13, 2016.

Copyright Notice

Copyright (c) 2015 IETF Trust and the persons identified as the document authors. All rights reserved.

This document is subject to BCP 78 and the IETF Trust’s Legal Provisions Relating to IETF Documents (http://trustee.ietf.org/license-info) in effect on the date of publication of this document.
1. Introduction

This document specifies a Hypertext Transfer Protocol (HTTP) status code for use when a server operator has received a legal demand to deny access to a resource or to a set of resources which includes the requested resource.

This status code can be used to provide transparency in circumstances where issues of law or public policy affect server operations. This transparency may be beneficial both to these operators and to end users.

[RFC4924] discusses the forces working against transparent operation of the Internet; these clearly include legal interventions to restrict access to content. As that document notes, and as Section 4 of [RFC4084] states, such restrictions should be made explicit.

Feedback should occur on the ietf-http-wg@w3.org mailing list.

2. Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].
3. 451 Unavailable For Legal Reasons

This status code indicates that the server is denying access to the resource as a consequence of a legal demand.

The server in question might not be an origin server. This type of legal demand typically most directly affects the operations of ISPs and search engines.

Responses using this status code SHOULD include an explanation, in the response body, of the details of the legal demand: the party making it, the applicable legislation or regulation, and what classes of person and resource it applies to. For example:

```
HTTP/1.1 451 Unavailable For Legal Reasons
Link: <https://spqr.example.org/legislatione>; rel="blocked-by"
Content-Type: text/html

<html>
<head><title>Unavailable For Legal Reasons</title></head>
<body>
<h1>Unavailable For Legal Reasons</h1>
<p>This request may not be serviced in the Roman Province of Judea due to the Lex Julia Majestatis, which disallows access to resources hosted on servers deemed to be operated by the People’s Front of Judea.</p>
</body>
</html>
```

The use of the 451 status code implies neither the existence nor non-existence of the resource named in the request. That is to say, it is possible that if the legal demands were removed, a request for the resource still might not succeed.

Note that in many cases clients can still access the denied resource by using technical countermeasures such as a VPN or the Tor network.

A 451 response is cacheable by default; i.e., unless otherwise indicated by the method definition or explicit cache controls; see [RFC7234].

4. Identifying Blocking Entities

As noted above, when an attempt to access a resource fails with status 451, the entity blocking access might or might not be the origin server. There are a variety of entities in the resource-
access path which could choose to deny access, for example ISPs, cache providers, and DNS servers.

It is useful, when legal blockages occur, to be able to identify the entities actually implementing the blocking.

When an entity blocks access to a resource and returns status 451, it SHOULD include a "Link" HTTP header field [RFC5988] whose value is a URI reference [RFC3986] identifying itself. When used for this purpose, the "Link" header field MUST have a "rel" parameter whose value is "blocked-by".

The intent is that the header be used to identify the entity actually implementing blockage, not any other entity mandating it. A human readable response body, as discussed above, is the appropriate location for discussion of administrative and policy issues.

5. Security Considerations

Clients cannot rely upon the use of the 451 status code. It is possible that certain legal authorities might wish to avoid transparency, and not only demand the restriction of access to certain resources, but also avoid disclosing that the demand was made.

6. IANA Considerations

The HTTP Status Codes Registry should be updated with the following entry:

- Code: 451
- Description: Unavailable for Legal Reasons
- Specification: [this document]

The Link Relation Type Registry should be updated with the following entry:

- Relation Name: blocked-by
- Description: Identifies the entity blocking access to a resource following on receipt of a legal demand.
- Reference: This document
7. References

7.1. Normative References

7.2. Informative References

Appendix A. Acknowledgements

Thanks to Terence Eden, who observed that the existing status code 403 was not really suitable for this situation, and suggested the creation of a new status code.

Thanks also to Ray Bradbury.

The ORIGIN HTTP/2 Frame
draft-nottingham-httpbis-origin-frame-00

Abstract

This document specifies the ORIGIN frame for HTTP/2, to indicate what origins are available on a given connection.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 21, 2016.

Please review these documents carefully, as they describe your rights and restrictions with respect to this document. Code Components extracted from this document must include Simplified BSD License text as described in Section 4.e of the Trust Legal Provisions and are provided without warranty as described in the Simplified BSD License.
Introduction

HTTP/2 [RFC7540] allows clients to coalesce different origins [RFC6454] onto the same connection when certain conditions are met. In some cases, the server is not authoritative for a coalesced origin, so the 421 (Misdirected Request) status code was defined.

Using a status code in this manner allows clients to recover from misdirected requests, but at the penalty of adding latency. To address that, this specification defines a new HTTP/2 frame type, "ORIGIN", to allow servers to indicate what origins a connection is authoritative for.

Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The ORIGIN HTTP/2 Frame

The ORIGIN HTTP/2 frame ([RFC7540], Section 4) indicates what origin(s) [RFC6454] the sender considers this connection authoritative for (in the sense of [RFC7540], Section 10.1).

The ORIGIN frame is a non-critical extension to HTTP/2. Endpoints that do not support this frame can safely ignore it.

It MUST occur on stream 0; an ORIGIN frame on any other stream is invalid and MUST be ignored.

When received by a client, it can be used to inform HTTP/2 connection coalescing (see [RFC7540], Section 9.1.1), but does not relax the requirement there that the server is authoritative.

If multiple ORIGIN frames are received on the same connection, only the most recent is to be considered current.
Once an ORIGIN frame has been received and processed, clients that implement this specification SHOULD NOT use that connection for a given origin if it did not appear within the current ORIGIN frame.

The ORIGIN frame type is 0xb (decimal 11).

+-------------------------------+-------------------------------+
|         Origin-Len (16)       | Origin? (*)                 ...
+-------------------------------+-------------------------------+

The ORIGIN frame contains the following fields, sets of which may be repeated within the frame to indicate multiple origins:

Origin-Len: An unsigned, 16-bit integer indicating the length, in octets, of the Origin field.
Origin: An optional sequence of characters containing the ASCII serialization of an origin ([RFC6454], Section 6.2) that the sender believes this connection is authoritative for.

The ORIGIN frame does not define any flags. It can contain one or more Origin-Len/Origin pairs.

The ORIGIN frame is processed hop-by-hop. An intermediary must not forward ORIGIN frames.

Clients configured to use a proxy MUST ignore any ORIGIN frames received from it.

2. Security Considerations

Clients that blindly trust the ORIGIN frame’s contents will be vulnerable to a large number of attacks; hence the reinforcement that this specification does not relax the requirement for server authority in [RFC7540], Section 10.1.

A JSON Encoding for HTTP Header Field Values
draft-reschke-http-jfv-02

Abstract

This document establishes a convention for use of JSON-encoded field values in HTTP header fields.

Editorial Note (To be removed by RFC Editor before publication)

Distribution of this document is unlimited. Although this is not a work item of the HTTPbis Working Group, comments should be sent to the Hypertext Transfer Protocol (HTTP) mailing list at ietf-http-wg@w3.org [1], which may be joined by sending a message with subject "subscribe" to ietf-http-wg-request@w3.org [2].

Discussions of the HTTPbis Working Group are archived at <http://lists.w3.org/Archives/Public/ietf-http-wg/>.

The changes in this draft are summarized in Appendix A.2.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

1. Introduction

Defining syntax for new HTTP header fields ([RFC7230], Section 3.2) is non-trivial. Among the commonly encountered problems are:

- There is no common syntax for complex field values. Several well-known header fields do use a similarly looking syntax, but it is hard to write generic parsing code that will both correctly handle valid field values but also reject invalid ones.

- The HTTP message format allows header fields to repeat, so field syntax needs to be designed in a way that these cases are either meaningful, or can be unambiguously detected and rejected.

- HTTP/1.1 does not define a character encoding scheme ([RFC6365], Section 2), so header fields are either stuck with US-ASCII ([RFC0020]), or need out-of-band information to decide what encoding scheme is used. Furthermore, APIs usually assume a default encoding scheme in order to map from octet sequences to strings (for instance, [XMLHttpRequest] uses the IDL type "ByteString", effectively resulting in the ISO-8859-1 character encoding scheme [ISO-8859-1] being used).

(See Section 8.3.1 of [RFC7231] for a summary of considerations for new header fields.)

This specification addresses the issues listed above by defining both a generic JSON-based ([RFC7159]) data model and a concrete wire format that can be used in definitions of new header fields.

2. Data Model and Format

In HTTP, header fields with the same field name can occur multiple times within a single message (Section 3.2.2 of [RFC7230]). When this happens, recipients are allowed to combine the field values using commas as delimiter. This rule matches nicely JSON's array format (Section 5 of [RFC7159]). Thus, the basic data model used here is the JSON array.

Header field definitions that need only a single value can restrict themselves to arrays of length 1, and are encouraged to define error handling in case more values are received (such as "first wins", "last wins", or "abort with fatal error message").

JSON arrays are mapped to field values by creating a sequence of serialized member elements, separated by commas and optionally whitespace. This is equivalent to using the full JSON array format, while leaving out the "begin-array" (‘[’) and "end-array" (‘]’).
The ABNF character names and classes below are used (copied from [RFC5234], Appendix B.1):

   CR         = %x0D    ; carriage return
   HTAB       = %x09    ; horizontal tab
   LF         = %x0A    ; line feed
   SP         = %x20    ; space
   VCHAR      = %x21-7E ; visible (printing) characters

Characters in JSON strings that are not allowed or discouraged in HTTP header field values -- that is, not in the "VCHAR" definition -- need to be represented using JSON's "backslash" escaping mechanism ([RFC7159], Section 7).

The control characters CR, LF, and HTAB do not appear inside JSON strings, but can be used outside (line breaks, indentation etc). These characters need to be either stripped or replaced by space characters (ABNF "SP").

Formally, using the HTTP specification’s ABNF extensions defined in Section 7 of [RFC7230]:

    json-field-value = #json-field-item
    json-field-item  = JSON-Text
                      ; see [RFC7159], Section 2,
                      ; post-processed so that only VCHAR characters
                      ; are used

3. Sender Requirements

To map a JSON array to an HTTP header field value, process each array element separately by:

1. generating the JSON representation,

2. stripping all JSON control characters (CR, HTAB, LF), or replacing them by space ("SP") characters,

3. replacing all remaining non-VSPACE characters by the equivalent backslash-escape sequence ([RFC7159], Section 7).

The resulting list of strings is transformed into an HTTP field value by combining them using comma (%x2C) plus optional SP as delimiter, and encoding the resulting string into an octet sequence using the US-ASCII character encoding scheme ([RFC0020]).
4. Recipient Requirements

To map a set of HTTP header field instances to a JSON array:

1. combine all header field instances into a single field as per Section 3.2.2 of [RFC7230],
2. add a leading begin-array ("[") octet and a trailing end-array ("]") octet, then
3. run the resulting octet sequence through a JSON parser.

The result of the parsing operation is either an error (in which case the header field values needs to be considered invalid), or a JSON array.

5. Using this Format in Header Field Definitions

[[anchor5: Explain what a definition of a new header field needs to do precisely to use this format, mention must-ignore extensibility]]

6. Examples

This section shows how some of the existing HTTP header fields would look like if they would use the format defined by this specification.

6.1. Content-Length

"Content-Length" is defined in Section 3.3.2 of [RFC7230], with the field value’s ABNF being:

    Content-Length = 1*DIGIT

So the field value is similar to a JSON number ([RFC7230], Section 6).

Content-Length is restricted to a single field instance, as it doesn’t use the list production (as per Section 3.2.2 of [RFC7230]). However, in practice multiple instances do occur, and the definition of the header field does indeed discuss how to handle these cases.

If Content-Length was defined using the JSON format discussed here, the ABNF would be something like:

    Content-Length = #number
    ; number: [RFC7159], Section 6

...and the prose definition would:
o restrict all numbers to be non-negative integers without fractions, and

o require that the array of values is of length 1 (but allow the case where the array is longer, but all members represent the same value)

6.2.  Content-Disposition

Content-Disposition field values, defined in [RFC6266], consist of a "disposition type" (a string), plus multiple parameters, of which at least one ("filename") sometime needs to carry non-ASCII characters.

For instance, the first example in Section 5 of [RFC6266]:

    Attachment; filename=example.html

has a disposition type of "Attachment", with filename parameter value "example.html". A JSON representation of this information might be:

```
{  
    "Attachment":{  
        "filename": "example.html"  
    }  
}
```

which would translate to a header field value of:

```
{ "Attachment": {  "filename" : "example.html" } }
```

The third example in Section 5 of [RFC6266] uses a filename parameter containing non-US-ASCII characters:

    attachment; filename*=UTF-8''%e2%82%ac%20rates

Note that in this case, the "filename*" parameter uses the encoding defined in [RFC5987], representing a filename starting with the Unicode character U+20AC (EURO SIGN), followed by " rates". If the definition of Content-Disposition would have used the format proposed here, the workaround involving the "parameter*" syntax would not have been needed at all.

The JSON representation of this value could then be:

```
{ "attachment": {  "filename" : "\u20AC rates" } }
```
6.3. WWW-Authenticate

The WWW-Authenticate header field value is defined in Section 4.1 of [RFC7235] as a list of "challenges":

WWW-Authenticate = 1#challenge

...where a challenge consists of a scheme with optional parameters:

challenge = auth-scheme [ 1*SP ( token68 / #auth-param ) ]

An example for a complex header field value given in the definition of the header field is:

Newauth realm="apps", type=1, title="Login to "apps"",
Basic realm="simple"

(line break added for readability)

A possible JSON representation of this field value would be the array below:

[
    {
        "Newauth" : {
            "realm": "apps",
            "type" : 1,
            "title" : "Login to "apps"
        }
    },
    {
        "Basic" : {
            "realm": "simple"
        }
    }
]

...which would translate to a header field value of:

{ "Newauth" : { "realm": "apps", "type" : 1, "title": "Login to "apps"" }},
{ "Basic" : { "realm": "simple"}}

7. Discussion

This approach uses a default of "JSON array", using implicit array markers. An alternative would be a default of "JSON object". This would simplify the syntax for non-list-typed header fields, but all
the benefits of having the same data model for both types of header fields would be gone. A hybrid approach might make sense, as long as it doesn’t require any heuristics on the recipient’s side. 

[[anchor7: Use of generic libs vs compactness of field values..]]

8. Deployment Considerations

This JSON-based syntax will only apply to newly introduced header fields, thus backwards compatibility is not a problem. That being said, it is conceivable that there is existing code that might trip over double quotes not being used for HTTP’s quoted-string syntax (Section 3.2.6 of [RFC7230]).

9. Internationalization Considerations

[[anchor10: TBD, mention migration path to message format that is robust wrt UTF-8, or other binary encodings of JSON]]

10. Security Considerations

Using JSON-shaped field values is believed to not introduce any new threads beyond those described in Section 12 of [RFC7159], namely the risk of recipients using the wrong tools to parse them.

Other than that, any syntax that makes extensions easy can be used to smuggle information through field values; however, this concern is shared with other widely used formats, such as those using parameters in the form of name/value pairs.

Abstract

The "Accept-Push-Policy" and "Push-Policy" header fields enable a client and a server to negotiate the behaviour of the server regarding the usage of push on a per-request basis.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

1. Introduction

HTTP/2 [RFC7540], the new version of the HTTP protocol, not only provides significant improvements compared to HTTP/1.1 (see [RFC7230] and [RFC7231]), but also provides several new features. Among these is Server Push, which enables a server to send responses to a client without having received the corresponding requests.

The range of possibilities offered by Server Push is a new domain wide open for experimentation. A first usage was foreseen early in the addition of this feature into HTTP/2, which is to replace the inlining of sub-resources inside a main resource, by pushing these sub-resources in response to the request for the main resource. As
described in [HighPerformance], with HTTP/1.1 a web designer may want to optimize the page load time by packing a whole web page into a single HTTP response. This can be achieved by inlining the CSS, JavaScript, and images inside the HTML document. By removing the need for the client to send requests for these sub-resources, this inlining technique can reduce the page load time by roughly a RTT. With HTTP/2, the same results can be obtained by pushing the sub-resources instead of inlining them. Using push has the advantage of keeping each sub-resource independent.

HTTP/2 provides a few ways of controlling Server Push from the client side. First, the SETTINGS parameter "SETTINGS_ENABLE_PUSH" allows a client to globally enable or disable push on a HTTP/2 connection. In addition, HTTP/2 Flow Control can be used to limit the bandwidth used by pushed resources.

These options provide only a coarse control of the usage of Server Push from the client side. In some cases, a more fine-grained control would be useful. This document describes several use cases where controlling Server Push would be useful for the client. It then proposes new header fields for realizing this control.

1.1. Terminology

In this document, the key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" are to be interpreted as described in BCP 14, RFC 2119 [RFC2119] and indicate requirement levels for compliant implementations.

This document uses the Augmented BNF defined in [RFC5234].

2. Push Control Use Cases

2.1. Adapting Push Behaviour

A browser may want to ask the server to adapt its behaviour for pushing resources depending on the user’s actions. For example, after navigating through a site for some time, the browser may have many sub-resources in its cache and may prefer that the server doesn’t push sub-resources anymore to prevent wasting bandwidth. This could be further optimized with the browser asking the server to push only response metadata (i.e., the responses pushed by the server correspond to requests made with the HEAD method instead of requests made with the GET method). By receiving in advance the list of sub-resources corresponding to a specific request, the browser would be able to fetch early on any missing sub-resource.
As another example, when a user opens many pages on the same site, the browser may want to receive pushed sub-resources only for the foreground tab and not for any background tab. This results in a better optimization of the page load time for the tab that is visible to the user.

2.2. Load Balancer

A second use case is a load balancer serving both HTTP/1.1 and HTTP/2 clients, and using HTTP/2 to connect to the backend servers, as described in [LoadBalancer].

The load balancer uses the same HTTP/2 connection towards a backend server to forward the requests received from several clients. When the client is a HTTP/1.1 client, the load balancer doesn’t want the backend server to push any resource in response to the client’s request. On the contrary, when the client is a HTTP/2 client, the load balancer would like the backend server to push sub-resources associated to the client’s request.

The load balancer would like to be able to enable or disable push on a per-request basis. This would enable it to optimize the server behaviour depending on the client’s capacity.

2.3. DASH Fast Start

Controlling the server behaviour regarding push may also be useful for specific applications. As an example, DASH [DASH] is a technology for streaming media content over HTTP. The media content is split into small file-based segments that can be retrieved through HTTP requests. Potentially, the media content is made available with different quality levels. A media presentation description (MPD) describes the organization of the media.

To render a media, a DASH client needs to first download the MPD, process it, and then request the necessary media segments. When requesting a MPD to play the associated media content, it would be useful for a DASH client to be able to ask the server to push some initial content (for example, the initialization segments, and possibly the first content segments).

However, there are also cases when it is not useful for the DASH client to receive in advance this initial content. For example, in a video program guide, the DASH client may want to download several MPDs corresponding to different media content, but doesn’t want to receive the initial content for all of these. Therefore, it is useful for the DASH client to be able to specify in a request for a MPD whether it wants the server to push some initial content.
In addition, when the DASH client asks the server to push some initial content, it could be useful for it to have some feedback from the server. This feedback would indicate whether the server is intending to push this initial content. The client could adapt its behaviour depending on this indication. For example, the client could start rendering the media sooner if it knows that the server is pushing the initial content.

2.4. Fast Page Load

The previous use case can be expanded to the more generic use case of downloading quickly a web page. As described in [Breaking1000msBarrier], it is important for the user perception to keep the perceived latency of loading a web page under 1000 ms. This can be difficult when using a mobile connection with a high latency. Part of the solution proposed in [Breaking1000msBarrier] for HTTP/1.1 is to inline all the sub-resources necessary for achieving a first rendering of the web page. With HTTP/2, the inlining of these sub-resources can be replaced by having the server push them.

Therefore, a client detecting that it is using a high-latency network could improve the user perceived latency by asking the server to push all the sub-resources necessary for a first display of a web page.

2.5. Use Cases Requirements

The analysis of these use cases enables to build a list of requirements for defining a fine-grained control over the usage of push by a server.

- The client can ask the server not to push any resource in response to a request.
- The client can ask the server to only push response metadata.
- The client can ask the server to use an application-defined behaviour regarding push.
- The server can indicate to the client its behaviour regarding push when processing a request.

3. Push Policy

A _push policy_ defines the server behaviour regarding push when processing a request. Different push policies can be used when processing different requests.
This section defines new header fields enabling a client and a server to negotiate the push policy used by the server to process a given request.

The new "Accept-Push-Policy" header field enables a client to express its expectations regarding the server’s push policy for processing a request.

The "Push-Policy" header field enables a server to state the push policy used when processing a request.

3.1. The Accept-Push-Policy Header Field

A client can express the desired push policy for a request by sending an "Accept-Push-Policy" header field in the request.

Accept-Push-Policy = token ; a push policy name

The header field value contains the push policy that the client expects the server to use when processing the request.

Possibly, the "Accept-Push-Policy" header field could be extended to support carrying multiple policies, as a comma-separated list of tokens. The server could choose its preferred policy among those proposed by the client.

3.2. Push-Policy Header Field

A server can indicate to a client the push policy it used when processing a request by sending a "Push-Policy" header field in the corresponding response.

Push-Policy = token ; a push policy name

The server MUST follow the indicated push policy when processing the client request associated to the response.

The "Push-Policy" header field can be used as an acknowledgement from the server after receiving a request containing the "Accept-Push-Policy" header field.

If the "Accept-Push-Policy" header field can contain a list of push policy names, the "Push-Policy" header field can be used to express which push policy was selected by the server.
The server can also choose a push policy not corresponding to the client’s expectation as expressed in the "Accept-Push-Policy" header, and specify the selected push policy in the "Push-Policy" header field.

3.3. Push Policy Values

This section defines some generic push policies. Other push policies can be standardized for either a generic usage, or for an application-specific usage. In addition, private push policies can be used by a web application.

TBD: select the form of private push policies (URN, "X-" values...).

3.3.1. None Push Policy

The "None" push policy value indicates that no resource is pushed when processing a request.

For example, a browser sending a request for a background tab could ask the server not to push any resources in response to this request by sending an "Accept-Push-Policy" header with the "None" value. This would result in the following HTTP/2 header block:

```
:method = GET
:scheme = https
:path = /index.html
:host = example.org
:accept = text/html
:accept-push-policy = none
```

3.3.2. Head Push Policy

The "Head" push policy value indicates that only response metadata are pushed (the server is pushing responses corresponding to requests made with the HEAD method).

For example, a browser may already have many resources from a web site in its cache. It could ask the server to push only response metadata. This would allow the browser to know early on the resources useful for rendering a web page (i.e., before receiving and parsing the HTML document), without taking the risk of wasting bandwidth with resources already in its cache. In this example, the browser’s request would contain the following HTTP/2 header block:

```
:method = GET
:scheme = https
```
3.3.3. Default Push Policy

The "Default" push policy value indicates that the server is using its default behaviour for pushing resources when processing a request.

For example, a server not fulfilling a client’s expectation regarding the push policy could indicate this with the "Default" push policy. It would send the following HTTP/2 header block in its response:

```plaintext
:status 200
push-policy = default
```

3.3.4. Fast-Load Push Policy

The "Fast-Load" push policy value indicates that the sub-resources necessary for a first rendering of a main resource are pushed alongside the response containing this main resource.

A server using the "Fast-Load" push policy while processing a request can push sub-resources not necessary for a first rendering, but SHOULD prioritize sub-resources necessary for this first rendering.

For example, a client detecting that it is using a high-latency network can try to improve the user perceived latency by asking the server to push the sub-resources necessary for a first rendering of a main page by including an "Accept-Push-Policy" header with the "Fast-Load" value. This would result in the following HTTP/2 header block:

```plaintext
:method = GET
:scheme = https
:path = /index.html
:host = example.org
:accept = text/html
:accept-push-policy = fast-load
```

4. IANA Considerations

TBD
5. Security Considerations

Encrypted Content-Encoding for HTTP
draft-thomson-http-encryption-02

Abstract

This memo introduces a content-coding for HTTP that allows message payloads to be encrypted.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

1. Introduction

It is sometimes desirable to encrypt the contents of a HTTP message (request or response) so that when the payload is stored (e.g., with a HTTP PUT), only someone with the appropriate key can read it.
For example, it might be necessary to store a file on a server without exposing its contents to that server. Furthermore, that same file could be replicated to other servers (to make it more resistant to server or network failure), downloaded by clients (to make it available offline), etc. without exposing its contents.

These uses are not met by the use of TLS [RFC5246], since it only encrypts the channel between the client and server.

This document specifies a content-coding (Section 3.1.2 of [RFC7231]) for HTTP to serve these and other use cases.

This content-coding is not a direct adaptation of message-based encryption formats — such as those that are described by [RFC4880], [RFC5652], [RFC7516], and [XMLENC] — which are not suited to stream processing, which is necessary for HTTP. The format described here cleaves more closely to the lower level constructs described in [RFC5116].

To the extent that message-based encryption formats use the same primitives, the format can be considered as sequence of encrypted messages with a particular profile. For instance, Appendix A explains how the format is congruent with a sequence of JSON Web Encryption [RFC7516] values with a fixed header.

This mechanism is likely only a small part of a larger design that uses content encryption. How clients and servers acquire and identify keys will depend on the use case. Though a complete key management system is not described, this document defines an Encryption-Key header field that can be used to convey keying material.

1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

2. The "aesgcm128" HTTP Content Encoding

The "aesgcm128" HTTP content-coding indicates that a payload has been encrypted using Advanced Encryption Standard (AES) in Galois/Counter Mode (GCM) as identified as AEAD_AES_128_GCM in [RFC5116], Section 5.1. The AEAD_AES_128_GCM algorithm uses a 128 bit content encryption key.

When this content-coding is in use, the Encryption header field (Section 3) describes how encryption has been applied. The
Encryption-Key header field (Section 4) can be included to describe how the content encryption key is derived or retrieved.

The "aesgcm128" content-coding uses a single fixed set of encryption primitives. Cipher suite agility is achieved by defining a new content-coding scheme. This ensures that only the HTTP Accept-Encoding header field is necessary to negotiate the use of encryption.

The "aesgcm128" content-coding uses a fixed record size. The resulting encoding is a series of fixed-size records, with a final record that is one or more octets shorter than a fixed sized record.

```
+-------+      input of between rs-256
| data  |           and rs-1 octets
+-------+      (one fewer for the last record)
    v
+-------------+      add padding to form plaintext
| pad | data |
+-------------+      expands by 16 octets
    v
+---------------------+      encrypt with AEAD_AES_128_GCM
| ciphertext |
+---------------------+
```

The record size determines the length of each portion of plaintext that is enciphered, with the exception of the final record, which is necessarily smaller. The record size defaults to 4096 octets, but can be changed using the "rs" parameter on the Encryption header field.

AEAD_AES_128_GCM expands ciphertext to be 16 octets longer than its input plaintext. Therefore, the length of each enciphered record other than the last is equal to the value of the "rs" parameter plus 16 octets. A receiver MUST fail to decrypt if the final record ciphertext is 16 octets or less in size. Valid records always contain at least one byte of padding and a 16 octet authentication tag.

Each record contains between 1 and 256 octets of padding, inserted into a record before the enciphered content. Padding consists of a length byte, followed that number of zero-valued octets. A receiver MUST fail to decrypt if any padding octet other than the first is non-zero, or a record has more padding than the record size can accommodate.
The nonce for each record is a 96-bit value constructed from the record sequence number and the input keying material. Nonce derivation is covered in Section 3.3.

The additional data passed to each invocation of AEAD_AES_128_GCM is a zero-length octet sequence.

A sequence of full-sized records can be truncated to produce a shorter sequence of records with valid authentication tags. To prevent an attacker from truncating a stream, an encoder MUST append a record that contains only padding and is smaller than the full record size if the final record ends on a record boundary. A receiver MUST treat the stream as failed due to truncation if the final record is the full record size.

A consequence of this record structure is that range requests [RFC7233] and random access to encrypted payload bodies are possible at the granularity of the record size. However, without data from adjacent ranges, partial records cannot be used. Thus, it is best if records start and end on multiples of the record size, plus the 16 octet authentication tag size.

3. The Encryption HTTP Header Field

The "Encryption" HTTP header field describes the encrypted content encoding(s) that have been applied to a payload body, and therefore how those content encoding(s) can be removed.

The "Encryption" header field uses the extended ABNF syntax defined in Section 1.2 of [RFC7230] and the "parameter" rule from [RFC7231]

\[
\text{Encryption-val} = \#\text{encryption_params} \\
\text{encryption_params} = [ \text{parameter} *( \text{";"} \text{parameter} ) ]
\]

If the payload is encrypted more than once (as reflected by having multiple content-codings that imply encryption), each application of the content encoding is reflected in the Encryption header field, in the order in which they were applied.

The Encryption header MAY be omitted if the sender does not intend for the immediate recipient to be able to decrypt the payload body. Alternatively, the Encryption header field MAY be omitted if the sender intends for the recipient to acquire the header field by other means.

Servers processing PUT requests MUST persist the value of the Encryption header field, unless they remove the content-coding by decrypting the payload.
3.1. Encryption Header Field Parameters

The following parameters are used in determining the content encryption key that is used for encryption:

keyid: The "keyid" parameter contains a string that identifies the keying material that is used. The "keyid" parameter SHOULD be included, unless key identification is guaranteed by other means. The "keyid" parameter MUST be used if keying material included in an Encryption-Key header field is needed to derive the content encryption key.

salt: The "salt" parameter contains a base64 URL-encoded octets that is used as salt in deriving a unique content encryption key (see Section 3.2). The "salt" parameter MUST be present, and MUST be exactly 16 octets long when decoded. The "salt" parameter MUST NOT be reused for two different payload bodies that have the same input keying material; generating a random salt for every application of the content encoding ensures that content encryption key reuse is highly unlikely.

rs: The "rs" parameter contains a positive decimal integer that describes the record size in octets. This value MUST be greater than 1. If the "rs" parameter is absent, the record size defaults to 4096 octets.

3.2. Content Encryption Key Derivation

In order to allow the reuse of keying material for multiple different HTTP messages, a content encryption key is derived for each message. The content encryption key is derived from the decoded value of the "salt" parameter using the HMAC-based key derivation function (HKDF) described in [RFC5869] using the SHA-256 hash algorithm [FIPS180-2].

The decoded value of the "salt" parameter is the salt input to HKDF function. The keying material identified by the "keyid" parameter is the input keying material (IKM) to HKDF. Input keying material can either be prearranged, or can be described using the Encryption-Key header field (Section 4). The first step of HKDF is therefore:

\[ PRK = HMAC-SHA-256(salt, IKM) \]

AEAD_AES_128_GCM requires a 16 octet (128 bit) content encryption key, so the length (L) parameter to HKDF is 16. The info parameter is set to the ASCII-encoded string "Content-Encoding: aescm128". The second step of HKDF can therefore be simplified to the first 16 octets of a single HMAC:
CEK = HMAC-SHA-256(PRK, "Content-Encoding: aesgcm128" || 0x01)

3.3. Nonce Derivation

The nonce input to AEAD_AES_128_GCM is constructed for each record. The nonce for each record is a 12 octet (96 bit) value is produced from the record sequence number and a value derived from the input keying material.

The input keying material and salt values are input to HKDF with different info and length parameters. The info parameter for the nonce is the ASCII-encoded string "Content-Encoding: nonce" and the length (L) parameter is 12 octets.

The result is combined with the record sequence number - using exclusive or – to produce the nonce. The record sequence number (SEQ) is a 96-bit unsigned integer in network byte order that starts at zero.

Thus, the final nonce for each record is a 12 octet value:

NONCE = HMAC-SHA-256(PRK, "Content-Encoding: nonce" || 0x01) ^ SEQ

4. Encryption-Key Header Field

An Encryption-Key header field can be used to describe the input keying material used in the Encryption header field.

The Encryption-Key header field uses the extended ABNF syntax defined in Section 1.2 of [RFC7230] and the "parameter" rule from [RFC7231].

Encryption-Key-val = #encryption_key_params
encryption_key_params = [ parameter *( ".;" parameter ) ]

keyid: The "keyid" parameter corresponds to the "keyid" parameter in the Encryption header field.

aesgcm128: The "aesgcm128" parameter contains the URL-safe base64 [RFC4648] octets of the input keying material.

dh: The "dh" parameter contains an ephemeral Diffie-Hellman share. This form of the header field can be used to encrypt content for a specific recipient.

The input keying material used by the content-encoding key derivation (see Section 3.2) can be determined based on the information in the Encryption-Key header field. The method for key derivation depends on the parameters that are present in the header field.
The value or values provided in the Encryption-Key header field is valid only for the current HTTP message unless additional information indicates a greater scope.

Note that different methods for determining input keying material will produce different amounts of data. The HKDF process ensures that the final content encryption key is the necessary size.

Alternative methods for determining input keying material MAY be defined by specifications that use this content-encoding.

4.1. Explicit Key

The "aesgcm128" parameter is decoded and used as the input keying material for the "aesgcm128" content encoding. The "aesgcm128" parameter MUST decode to at least 16 octets in order to be used as input keying material for "aesgcm128" content encoding.

Other key determination parameters can be ignored if the "aesgcm128" parameter is present.

4.2. Diffie-Hellman

The "dh" parameter is included to describe a Diffie-Hellman share, either modp (or finite field) Diffie-Hellman [DH] or elliptic curve Diffie-Hellman (ECDH) [RFC4492].

This share is combined with other information at the recipient to determine the HKDF input keying material. In order for the exchange to be successful, the following information MUST be established out of band:

- Which Diffie-Hellman form is used.
- The modp group or elliptic curve that will be used.
- The format of the ephemeral public share that is included in the "dh" parameter. For instance, using ECDH both parties need to agree whether this is an uncompressed or compressed point.

In addition to identifying which content-encoding this input keying material is used for, the "keyid" parameter is used to identify this additional information at the receiver.

The intended recipient recovers their private key and are then able to generate a shared secret using the appropriate Diffie-Hellman process.
Specifications that rely on an Diffie-Hellman exchange for determining input keying material MUST either specify the parameters for Diffie-Hellman (group parameters, or curves and point format) that are used, or describe how those parameters are negotiated between sender and receiver.

5. Examples

5.1. Successful GET Response

HTTP/1.1 200 OK
Content-Type: application/octet-stream
Content-Encoding: aesgcm128
Connection: close
Encryption: keyid="http://example.org/bob/keys/123";
salt="XZwpw6o37R-6qoZjw6KwAw"

[encrypted payload]

Here, a successful HTTP GET response has been encrypted using input keying material that is identified by a URI.

Note that the media type has been changed to "application/octet-stream" to avoid exposing information about the content.

5.2. Encryption and Compression

HTTP/1.1 200 OK
Content-Type: text/html
Content-Encoding: aesgcm128, gzip
Transfer-Encoding: chunked
Encryption: keyid="mailto:me@example.com";
salt="m2hJ_NttRtFyUiMRPwfpHA"

[encrypted payload]

5.3. Encryption with More Than One Key
PUT /thing HTTP/1.1
Host: storage.example.com
Content-Type: application/http
Content-Encoding: aesgcm128, aesgcm128
Content-Length: 1234
Encryption: keyid="mailto:me@example.com";
salt="NfzOeuV5USPRA-n_9s1Lag",
keyid="http://example.org/bob/keys/123";
salt="bDMSGoc2uobK_IhavSHsHA"; rs=1200

[encrypted payload]

Here, a PUT request has been encrypted twice with different input keying material; decrypting twice is necessary to read the content. The outer layer of encryption uses a 1200 octet record size.

5.4. Encryption with Explicit Key

HTTP/1.1 200 OK
Content-Length: 32
Content-Encoding: aesgcm128
Encryption: keyid="a1"; salt="ibZx1RNz537h1XNkRcPpJA"
Encryption-Key: keyid="a1"; aesgcm128="9Z57YCb3dK95dSsdFJbkag"

zK3kpG__Z8whjIkG6RYgPz11oUkTKcxPy9WP-VPMfuc

This example shows the string "I am the walrus" encrypted using an directly provided value for the input keying material. The content body contains a single record only and is shown here encoded in URL-safe base64 for presentation reasons only.

5.5. Diffie-Hellman Encryption

HTTP/1.1 200 OK
Content-Length: 32
Content-Encoding: aesgcm128
Encryption: keyid="dhkey"; salt="5hpuYfxDzG6nSs9-EQuaBg"
Encryption-Key: keyid="dhkey";
dh="BLsyIPbDn6bquEOwHaju2gj8kUVoflzTtPs_6fGoock_
dwx11BcgFtObPVnic4alcEucx8I6G8HmEZCJnA136Zg"

BmuHqRzdD4W1mibxglrPiRHZRSY49Dzdm6jHrWXzZrE

This example shows the same string, "I am the walrus", encrypted using ECDH over the P-256 curve [FIPS186]. The content body is shown here encoded in URL-safe base64 for presentation reasons only.
The receiver (in this case, the HTTP client) uses a key pair that is identified by the string "dhkey" and the sender (the server) uses a key pair for which the public share is included in the "dh" parameter above. The keys shown below use uncompressed points [X.692] encoded using URL-safe base64. Line wrapping is added for presentation purposes only.

Receiver:
  private key: iCjNf8v4ox_glIrJuSs_gbNmYuUYx76zRruQs_CHRzDg
  public key: BPM1w41cSD4BMMeBTY0Fx9ryLM-LeM22Dnt0gaLRukf05
             rMhzFAvxVW_mipg50hWw492WW0uM02Nrd32v8oDQ
Sender:
  private key: W0cxgeHDZkR3uMQYAbVgF5swKQUAR7DoTaaQVI-Fg
  public key: <the value of the "dh" parameter>

6. Security Considerations

This mechanism assumes the presence of a key management framework that is used to manage the distribution of keys between valid senders and receivers. Defining key management is part of composing this mechanism into a larger application, protocol, or framework.

Implementation of cryptography - and key management in particular - can be difficult. For instance, implementations need to account for the potential for exposing keying material on side channels, such as might be exposed by the time it takes to perform a given operation. The requirements for a good implementation of cryptographic algorithms can change over time.

6.1. Key and Nonce Reuse

Encrypting different plaintext with the same content encryption key and nonce in AES-GCM is not safe [RFC5116]. The scheme defined here uses a fixed progression of nonce values. Thus, a new content encryption key is needed for every application of the content encoding. Since input keying material can be reused, a unique "salt" parameter is needed to ensure a content encryption key is not reused.

If a content encryption key is reused - that is, if input keying material and salt are reused - this could expose the plaintext and the authentication key, nullifying the protection offered by encryption. Thus, if the same input keying material is reused, then the salt parameter MUST be unique each time. This ensures that the content encryption key is not reused. An implementation SHOULD generate a random salt parameter for every message; a counter could achieve the same result.
6.2. Content Integrity

This mechanism only provides content origin authentication. The authentication tag only ensures that an entity with access to the content encryption key produced the encrypted data.

Any entity with the content encryption key can therefore produce content that will be accepted as valid. This includes all recipients of the same HTTP message.

Furthermore, any entity that is able to modify both the Encryption header field and the HTTP message body can replace the contents. Without the content encryption key or the input keying material, modifications to or replacement of parts of a payload body are not possible.

6.3. Leaking Information in Headers

Because only the payload body is encrypted, information exposed in header fields is visible to anyone who can read the HTTP message. This could expose side-channel information.

For example, the Content-Type header field can leak information about the payload body.

There are a number of strategies available to mitigate this threat, depending upon the application’s threat model and the users’ tolerance for leaked information:

1. Determine that it is not an issue. For example, if it is expected that all content stored will be "application/json", or another very common media type, exposing the Content-Type header field could be an acceptable risk.

2. If it is considered sensitive information and it is possible to determine it through other means (e.g., out of band, using hints in other representations, etc.), omit the relevant headers, and/or normalize them. In the case of Content-Type, this could be accomplished by always sending Content-Type: application/octet-stream (the most generic media type), or no Content-Type at all.

3. If it is considered sensitive information and it is not possible to convey it elsewhere, encapsulate the HTTP message using the application/http media type (Section 8.3.2 of [RFC7230]), encrypting that as the payload of the "outer" message.
6.4. Poisoning Storage

This mechanism only offers encryption of content; it does not perform authentication or authorization, which still needs to be performed (e.g., by HTTP authentication [RFC7235]).

This is especially relevant when a HTTP PUT request is accepted by a server; if the request is unauthenticated, it becomes possible for a third party to deny service and/or poison the store.

6.5. Sizing and Timing Attacks

Applications using this mechanism need to be aware that the size of encrypted messages, as well as their timing, HTTP methods, URIs and so on, may leak sensitive information.

This risk can be mitigated through the use of the padding that this mechanism provides. Alternatively, splitting up content into segments and storing the separately might reduce exposure. HTTP/2 [RFC7540] combined with TLS [RFC5246] might be used to hide the size of individual messages.

7. IANA Considerations

7.1. The "aesgcm128" HTTP Content Encoding

This memo registers the "encrypted" HTTP content-coding in the HTTP Content Codings Registry, as detailed in Section 2.

- Name: aesgcm128
- Description: AES-GCM encryption with a 128-bit content encryption key
- Reference: this specification

7.2. Encryption Header Fields

This memo registers the "Encryption" HTTP header field in the Permanent Message Header Registry, as detailed in Section 3.

- Field name: Encryption
- Protocol: HTTP
- Status: Standard
- Reference: this specification
This memo registers the "Encryption-Key" HTTP header field in the Permanent Message Header Registry, as detailed in Section 4.

Field name: Encryption-Key
Protocol: HTTP
Status: Standard
Reference: this specification

7.3. The HTTP Encryption Parameter Registry

This memo establishes a registry for parameters used by the "Encryption" header field under the "Hypertext Transfer Protocol (HTTP) Parameters" grouping. The "Hypertext Transfer Protocol (HTTP) Encryption Parameters" operates under an "Specification Required" policy [RFC5226].

Entries in this registry are expected to include the following information:

Parameter Name: The name of the parameter.
Purpose: A brief description of the purpose of the parameter.
Reference: A reference to a specification that defines the semantics of the parameter.

The initial contents of this registry are:

7.3.1. keyid
Parameter Name: keyid
Purpose: Identify the key that is in use.
Reference: this document

7.3.2. salt
Parameter Name: salt
7.3.3. rs

- **Parameter Name**: rs
- **Purpose**: The size of the encrypted records.
- **Reference**: this document

7.4. The HTTP Encryption-Key Parameter Registry

This memo establishes a registry for parameters used by the "Encryption-Key" header field under the "Hypertext Transfer Protocol (HTTP) Parameters" grouping. The "Hypertext Transfer Protocol (HTTP) Encryption Parameters" operates under an "Specification Required" policy [RFC5226].

Entries in this registry are expected to include the following information:

- **Parameter Name**: The name of the parameter.
- **Purpose**: A brief description of the purpose of the parameter.
- **Reference**: A reference to a specification that defines the semantics of the parameter.

The initial contents of this registry are:

7.4.1. keyid

- **Parameter Name**: keyid
- **Purpose**: Identify the key that is in use.
- **Reference**: this document

7.4.2. aesgcm128

- **Parameter Name**: aesgcm128
- **Purpose**: Provide an explicit input keying material value for the aesgcm128 content encoding.
7.4.3. dh

- Parameter Name: dh
- Purpose: Carry a modp or elliptic curve Diffie-Hellman share used to derive input keying material.

8. References

8.1. Normative References

8.2. Informative References

Appendix A.  JWE Mapping

The "aesgcm128" content encoding can be considered as a sequence of JSON Web Encryption (JWE) objects [RFC7516], each corresponding to a single fixed size record.  The following transformations are applied to a JWE object that might be expressed using the JWE Compact Serialization:

- The JWE Protected Header is fixed to a value { "alg": "dir", "enc": "A128GCM" }, describing direct encryption using AES-GCM with a 128-bit content encryption key.  This header is not transmitted, it is instead implied by the value of the Content-Encoding header field.

- The JWE Encrypted Key is empty, as stipulated by the direct encryption algorithm.

- The JWE Initialization Vector ("iv") for each record is set to the exclusive or of the 96-bit record sequence number, starting at zero, and a value derived from the input keying material (see Section 3.3).  This value is also not transmitted.

- The final value is the concatenated JWE Ciphertext and the JWE Authentication Tag, both expressed without URL-safe Base 64 encoding.  The "." separator is omitted, since the length of these fields is known.

Thus, the example in Section 5.4 can be rendered using the JWE Compact Serialization as:

eyAiyWxnIjogImRpciISICJlbmMiOiAiQTEyOEEdTSIGfQ..AAAAAABBBBBBBB.
LwTC-fwdKh8de0smD2jizA.eh1vURhu6SM2lxhctbbntA

Where the first line represents the fixed JWE Protected Header, JWE Encrypted Key, and JWE Initialization Vector, all of which are
determined algorithmically. The second line contains the encoded body, split into JWE Ciphertext and JWE Authentication Tag.

Internet-Draft
Updates: 6265 (if approved)
Intended status: Standards Track
Expires: April 14, 2016

Cookie Prefixes
draft-west-cookie-prefixes-04

Abstract

This document updates RFC6265 by adding a set of restrictions upon
the names which may be used for cookies with specific properties.
These restrictions enable user agents to smuggle cookie state to the
server within the confines of the existing "Cookie" request header
syntax, and limits the ways in which cookies may be abused in a
conforming user agent.

Status of This Memo

This Internet-Draft is submitted in full conformance with the
provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering
Task Force (IETF). Note that other groups may also distribute
working documents as Internet-Drafts. The list of current Internet-
Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months
and may be updated, replaced, or obsoleted by other documents at any
time. It is inappropriate to use Internet-Drafts as reference
material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 14, 2016.

Provisions Relating to IETF Documents
(http://trustee.ietf.org/license-info) in effect on the date of
publication of this document. Please review these documents
carefully, as they describe your rights and restrictions with respect
to this document. Code Components extracted from this document must
include Simplified BSD License text as described in Section 4.e of
1. Introduction

Section 8.5 and Section 8.6 of [RFC6265] spell out some of the drawbacks of cookies’ implementation: due to historical accident, it is impossible for a server to have confidence that a cookie set in a secure way (e.g., as a domain cookie with the "Secure" (and possibly "HttpOnly") flags set) remains intact and untouched by non-secure subdomains.

We can’t alter the syntax of the "Cookie" request header, as that would likely break a number of implementations. This rules out sending a cookie’s flags along with the cookie directly, but we can smuggle information along with the cookie if we reserve certain name prefixes for cookies with certain properties.

This document describes such a scheme, which enables servers to set cookies which conforming user agents will ensure are "Secure", and locked to a domain.

2. Terminology and notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The "scheme" component of a URI is defined in Section 3 of [RFC3986].
3. Prefixes

3.1. The "$Secure-" prefix

If a cookie’s name begins with "$Secure-", the cookie MUST be:

1. Set with a "Secure" attribute
2. Set from a URI whose "scheme" is considered "secure" by the user agent.

The following cookie would be rejected when set from any origin, as the "Secure" flag is not set

Set-Cookie: $Secure-SID=12345; Domain=example.com

While the following would be accepted if set from a secure origin (e.g. "https://example.com/")), and rejected otherwise:

Set-Cookie: $Secure-SID=12345; Secure; Domain=example.com

3.2. The "$Host-" prefix

If a cookie’s name begins with "$Host-", the cookie MUST be:

1. Set with a "Secure" attribute
2. Set from a URI whose "scheme" is considered "secure" by the user agent.
3. Sent only to the host which set the cookie. That is, a cookie named "$Host-cookie1" set from "https://example.com" MUST NOT contain a "Domain" attribute (and will therefore be sent only to "example.com", and not to "subdomain.example.com").
4. Sent to every request for a host. That is, a cookie named "$Host-cookie1" MUST contain a "Path" attribute with a value of "/".

The following cookies would always be rejected:

Set-Cookie: $Host-SID=12345
Set-Cookie: $Host-SID=12345; Secure
Set-Cookie: $Host-SID=12345; Domain=example.com
Set-Cookie: $Host-SID=12345; Domain=example.com; Path=/
Set-Cookie: $Host-SID=12345; Secure; Domain=example.com; Path=/
While the following would be accepted if set from a secure origin (e.g. "https://example.com/"), and rejected otherwise:

Set-Cookie: $Host-SID=12345; Secure; Path=/

4. User Agent Requirements

This document updates Section 5.3 of [RFC6265] as follows:

After step 10 of the current algorithm, the cookies flags are set. Insert the following steps to perform the prefix checks this document specifies:

1. If the "cookie-name" begins with the string "$Secure-" or "$Host-", abort these steps and ignore the cookie entirely unless both of the following conditions are true:
   * The cookie’s "secure-only-flag" is "true"
   * "request-uri”’s "scheme" component denotes a "secure" protocol (as determined by the user agent)

2. If the "cookie-name" begins with the string "$Host-", abort these steps and ignore the cookie entirely unless the following conditions are true:
   * The cookie’s "host-only-flag" is "true"
   * The cookie’s "path" is "/"

5. Aesthetic Considerations

Prefixes are ugly. :(

6. Security Considerations

6.1. Secure Origins Only

It would certainly be possible to extend this scheme to non-secure origins (and an earlier draft of this document did exactly that). User agents, however, are slowly moving towards a world where features with security implications are available only over secure transport (see [SECURE-CONTEXTS], [POWERFUL-FEATURES], and [DEPRECATING-HTTP]). This document follows that trend, limiting exciting new cookie properties to secure transport in order to ensure that user agents can make claims which middlemen will have a hard time violating.
To that end, note that the requirements listed above mean that prefixed cookies will be rejected entirely if a non-secure origin attempts to set them.

6.2. Limitations

This scheme gives no assurance to the server that the restrictions on cookie names are enforced. Servers could certainly probe the user agent’s functionality to determine support, or sniff based on the "User-Agent" request header, if such assurances were deemed necessary.

7. References

7.1. Normative References

7.2. Informative References

Appendix A.  Acknowledgements

Eric Lawrence had this idea a million years ago, and wrote about its genesis in [Lawrence2015]. Devdatta Akhawe helped justify the potential impact of the scheme on real-world websites.

Abstract

This document updates RFC6265 by defining a "First-Party-Only" attribute which allows servers to assert that a cookie ought to be sent only in a "first-party" context. This assertion allows user agents to mitigate the risk of cross-origin information leakage, and provides some minimal protection against cross-site request forgery attacks.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Please review these documents carefully, as they describe your rights and restrictions with respect to this document. Code Components extracted from this document must include Simplified BSD License text as described in Section 4.e of
1. Introduction

Section 8.2 of [RFC6265] eloquently notes that cookies are a form of ambient authority, attached by default to requests the user agent sends on a user’s behalf. Even when an attacker doesn’t know the contents of a user’s cookies, she can still execute commands on the user’s behalf (and with the user’s authority) by asking the user agent to send HTTP requests to unwary servers.

Here, we update [RFC6265] with a simple mitigation strategy that allows servers to declare certain cookies as "First-party-only", meaning they should be attached to requests if and only if those requests occur in a first-party context (as defined in section 2.1).

Note that the mechanism outlined here is backwards compatible with the existing cookie syntax. Servers may serve first-party cookies to all user agents; those that do not support the "First-Party-Only"
attribute will simply store a cookie which is returned in all applicable contexts, just as they do today.

1.1. Goals

These first-party-only cookies are intended to provide a solid layer of defense-in-depth against attacks which require embedding an authenticated request into an attacker-controlled context:

1. Timing attacks which yield cross-origin information leakage (such as those detailed in [pixel-perfect]) can be substantially mitigated by setting the "First-Party-Only" attribute on authentication cookies. The attacker will only be able to embed unauthenticated resources, as embedding mechanisms such as 
"<iframe>" will not create first-party contexts.

2. Cross-site script inclusion (XSSI) attacks are likewise mitigated by setting the "First-Party-Only" attribute on authentication cookies. The attacker will not be able to include authenticated resources via "<script>" or "<link>", as these embedding mechanisms will not create first-party contexts.

First-party-only cookies also mitigate one specific kind of cross-site request forgery (CSRF) attack by treating cross-origin requests with unsafe methods (including top-level navigations) as as third-party requests.

Aside from these attack mitigations, first-party-only cookies can also be useful for policy or regulatory purposes. That is, it may be valuable for an origin to assert that its cookies should not be sent along with third-party requests in order to limit its exposure to non-technical risk.

1.2. Limitations

First-party-only cookies provide reasonable defense in depth against CSRF attacks that rely on unsafe HTTP methods (like "POST"). They do not offer a robust defense against CSRF as a general category of attack:

1. Attackers can still pop up new windows or trigger top-level navigations in order to create a first-party context (as described in section 2.1), which is only a speedbump along the road to exploitation.

2. Features like "<link rel='prerender'>" [prerendering] can be exploited to create first-party contexts without the risk of user detection.
In addition to the usual server-side defenses (CSRF tokens, ensuring that "safe" HTTP methods are idempotent, etc), client-side techniques such as those described in [app-isolation] may prove effective against CSRF, and are certainly worth exploring in combination with first-party-only cookies. First-party-only cookies on their own, however, are not a barrier to CSRF attacks as a general category.

1.3. Examples

First-party-only cookies are set via the "First-Party-Only" attribute in the "Set-Cookie" header field. That is, given a server’s response to a user agent which contains the following header field:

```
Set-Cookie: SID=31d4d96e407aad42; First-Party-Only
```

Subsequent requests from that user agent can be expected to contain the following header field if and only if both the requested resource and the resource in the top-level browsing context match the cookie.

2. Terminology and notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This specification uses the Augmented Backus-Naur Form (ABNF) notation of [RFC5234].

Two sequences of octets are said to case-insensitively match each other if and only if they are equivalent under the "i;ascii-casemap" collation defined in [RFC4790].

The terms "active document", "ancestor browsing context", "browsing context", "document", "iframe srcdoc document", "parent browsing context", and "top-level browsing context" are defined in the HTML Living Standard [HTML].

"Web Workers", "dedicated workers", "owner document", "list of relevant documents", and "shared workers" are defined in the Web Workers specification [WORKERS].

"Service Workers" are defined in the Service Workers specification [SERVICE-WORKERS].

The term "origin", the mechanism of deriving an origin from a URI, and the "the same" matching algorithm for origins are defined in [RFC6454].
"Safe" HTTP methods include "GET", "HEAD", "OPTIONS", and "TRACE", as defined in Section 4.2.1 of [RFC7231].

The term "public suffix" is defined in a note in Section 5.3 of [RFC6265] as "a domain that is controlled by a public registry". For example, "example.com"'s public suffix is "com". User agents SHOULD use an up-to-date public suffix list, such as the one maintained by Mozilla at [PSL].

An origin's "registerable domain" is the origin's host's public suffix plus the label to its left. That is, "https://www.example.com"'s registerable domain is "example.com". This concept is defined more rigorously in [PSL].

2.1. First-party and Third-party Requests

2.1.1. Document-based requests

When considering a request generated while parsing a document, or executing script in its context, we need to consider the document’s origin as well as the origin of each of it’s ancestors, in order to determine whether the request should be considered "first-party".

For this kind of request, the URI displayed in a user agent’s address bar is the only security context directly exposed to users, and therefore the only signal users can reasonably rely upon to determine whether or not they trust a particular website. The origin of that URI is, therefore, the "first-party origin".

In order to prevent the kinds of "multiple-nested scenarios" described in Section 4 of [RFC7034], we must check the first-party origin against the origins of each of a document’s ancestor browsing contexts’ active documents. A document is considered a "first-party context" if and only if the registerable domain of the origin of its URI is the same as the registerable domain of the first-party origin, and if each of the active documents in its ancestors’ browsing contexts’ is a first-party context.

This definition has a few implications:

- New windows create new first-party contexts (as the active document is rendered into a top-level browsing context).
- Full-page navigations create new first-party contexts. Notably, this includes both HTTP and "<meta>"-driven redirects.
To be more precise, given an HTTP request "request", the following algorithm returns "First-Party" if "request" is a first-party request, and "Third-Party" otherwise:

1. Let "document" be the document responsible for "request".

2. If "document" is a first-party context, and "request"’s URI’s origin’s registerable domain is the same the registerable domain of the origin of the URI of the active document in the top-level browsing context of "document", then return "First-Party".

3. Return "Third-Party".

Given a Document "document", the following algorithm returns "First-Party" if "document" is a first-party context, and "Third-Party" otherwise:

1. Let "top-origin" be the origin of the URI of the active document in the top-level browsing context of the document responsible for "request".

2. If "document"’s URI’s origin is not "top-origin", return "Third-Party".

3. While "document" has a parent browsing context:
   1. Let "document" be "document"’s parent browsing context’s active document.
   2. If "document"’s URI’s origin does not have the same registerable domain as "top-origin" and "document" is not an iframe srcdoc document, return "Third-Party".

4. Return "First-Party".

Note that we deal with the document’s location in steps 2, 3, and 4.2 above, not with the document’s origin. For example, a top-level document from "https://example.com" which has been sandboxed into a unique origin still creates a non-unique first-party context for subsequent requests.
2.1.2. Worker-based requests

Worker-driven requests aren’t as clear-cut as document-driven requests, as there isn’t a clear link between a top-level browsing context and a worker. This is especially true for Service Workers [SERVICE-WORKERS], which may execute code in the background, without any document visible at all.

Note: The descriptions below assume that workers must be same-origin with the documents that instantiate them. If this invariant changes, we’ll need to take the worker’s script’s URI into account when determining their status.

2.1.2.1. Dedicated Workers

Dedicated workers are fairly straightforward to categorize, as each dedicated worker is bound to one and only one Document. Requests generated from a dedicated worker (via "importScripts", "XMLHttpRequest", "fetch()", and so on) are first-party requests if and only if the worker’s owner document is a first-party context.

To be more precise, given an HTTP request "request", the following algorithm returns "First-Party" if "request" is a first-party request, and "Third-Party" otherwise:

1. Let "worker" be the dedicated worker responsible for "request".

2. Let "document" be "worker"’s owner document.

3. If "document" is a first-party context, and "request"’s URI’s origin’s registerable domain is the same as the registerable domain of the origin of the URI of the active document in the top-level browsing context of "document", then return "First-Party".

4. Return "Third-Party".

2.1.2.2. Shared Workers

Shared Workers introduce the complexity of bindings to multiple Documents. As it is quite possible for a shared worker to be bound at the same time to one Document that is a first-party context, and another that isn’t, we’ll need to walk through all the documents associated with the worker to determine its status. If and only if all associated documents are first-party contexts, then the worker is a first-party context.
To be more precise, given an HTTP request "request", the following algorithm returns "First-Party" if "request" is a first-party request, and "Third-Party" otherwise:

1. Let "worker" be the dedicated worker responsible for "request".
2. For each "document" in "worker"’s list of relevant Documents:
   1. Return "Third-Party" if "document" is not a first-party context (as defined in section 2.1.1).
   2. Return "Third-Party" if "request"’s URI’s origin’s registerable domain is not the same as the registerable domain of the origin of the URI of the active document in the top-level browsing context of "document".
3. Return "First-Party".

2.1.2.3. Service Workers

Service Workers are more complex still, as they act as a completely separate execution context, with very little relationship to the Document which registered them.

Until we have more implementation experience, we will consider Service Workers as third-party contexts in all cases.

Note: Requests which simply pass through a service worker will be handled as described above; the only requests which will be effected by this categorization are those which the service worker itself initiates (via "fetch()", for instance).

3. Server Requirements

This section describes extensions to [RFC6265] necessary to implement the server-side requirements of the "First-Party-Only" attribute.

3.1. Grammar

Add "First-Party-Only" to the list of accepted attributes in the "Set-Cookie" header field’s value by replacing the "cookie-av" token definition in Section 4.1.1 of [RFC6265] with the following ABNF grammar:

```
cookie-av     = expires-av / max-age-av / domain-av / path-av / secure-av / httponly-av / first-party-only-av / extension-av
first-party-only-av = "First-Party-Only"
```
3.2.  Semantics of the "First-Party-Only" Attribute (Non-Normative)

The "First-Party-Only" attribute limits the scope of the cookie such that it will only be attached to requests if those requests are "first-party", as described in Section 2.1. For example, requests for "https://example.com/sekrit-image" will attach first-party-only cookies if and only if the top-level browsing context is currently displaying a document from "https://example.com".

The changes to the "Cookie" header field suggested in Section 4.3 provide additional detail.

4.  User Agent Requirements

This section describes extensions to [RFC6265] necessary in order to implement the client-side requirements of the "First-Party-Only" attribute.

4.1.  The "First-Party-Only" attribute

The following attribute definition should be considered part of the the "Set-Cookie" algorithm as described in Section 5.2 of [RFC6265]:

If the attribute-name case-insensitively matches the string "First-Party-Only", the user agent MUST append an attribute to the "cookie-attribute-list" with an "attribute-name" of "First-Party-Only" and an empty "attribute-value".

4.2.  Monkey-patching the Storage Model

Note: There’s got to be a better way to specify this. Until I figure out what that is, monkey-patching!

Alter Section 5.3 of [RFC6265] as follows:

1.  Add "first-party-only-flag" to the list of fields stored for each cookie.

2.  Before step 11 of the current algorithm, add the following:

1.  If the "cookie-attribute-list" contains an attribute with an "attribute-name" of "First-Party-Only", set the cookie’s "first-party-only-flag" to true. Otherwise, set the cookie’s "first-party-only-flag" to false.

2.  If the cookie’s "first-party-only-flag" is set to true, and the request which generated the cookie is not a first-party
request (as defined in Section 2.1), then abort these steps and ignore the newly created cookie entirely.

4.3. Monkey-patching the "Cookie" header

Note: There’s got to be a better way to specify this. Until I figure out what that is, monkey-patching!

Alter Section 5.4 of [RFC6265] as follows:

1. Add the following requirements to the list in step 1:
   * If the cookie’s "first-party-only-flag" is true, then exclude the cookie if the HTTP request is a third-party request (see Section 2.1).
   * If the cookie’s "first-party-only-flag" is true, then exclude the cookie if the HTTP request’s method is not safe and the registerable domain of the origin of the URI of the document which originated the request is not the same as the registerable domain of the origin of the HTTP request’s URI.

Note that the modifications suggested here concern themselves only with the origins of ancestor browsing contexts and the origin of the resource being requested. The cookie’s "domain", "path", and "secure" attributes do not come into play for these comparisons.

5. Authoring Considerations

5.1. Mashups and Widgets

The "First-Party-Only" attribute is inappropriate for some important use-cases. In particular, note that content intended for embedding in a third-party context (social networking widgets or commenting services, for instance) will not have access to first-party-only cookies. Non-first-party cookies may be required in order to provide seamless functionality that relies on a user’s state.

Likewise, some forms of Single-Sign-On might require authentication in a third-party context; these mechanisms will not function as intended with first-party-only cookies.

6. Privacy Considerations

First-party-only cookies in and of themselves don’t do anything to address the general privacy concerns outlined in Section 7.1 of [RFC6265]. The attribute is set by the server, and serves to mitigate the risk of certain kinds of attacks that the server is
worried about. The user is not involved in this decision. Moreover, a number of side-channels exist which could allow a server to link distinct requests even in the absence of cookies. Connection and/or socket pooling, Token Binding, and Channel ID all offer explicit methods of identification that servers could take advantage of.

Abstract

This document updates RFC6265 by removing the ability for a non-secure origin to set cookies with a 'secure' flag, and to overwrite cookies whose 'secure' flag is set. This deprecation improves the isolation between HTTP and HTTPS origins, and reduces the risk of malicious interference.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 26, 2016.

1. Introduction

Section 8.5 and Section 8.6 of [RFC6265] spell out some of the drawbacks of cookies’ implementation: due to historical accident, non-secure origins can set cookies which will be delivered to secure origins in a manner indistinguishable from cookies set by that origin itself. This enables a number of attacks, which have been recently spelled out in some detail in [COOKIE-INTEGRITY].

We can mitigate the risk of these attacks by making it more difficult for non-secure origins to influence the state of secure origins. Accordingly, this document recommends the deprecation and removal of non-secure origins’ ability to write cookies with a ‘secure’ flag, and their ability to overwrite cookies whose ‘secure’ flag is set.

2. Terminology and notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The "scheme" component of a URI is defined in Section 3 of [RFC3986].

3. Recommendations

This document updates Section 5.3 of [RFC6265] as follows:

1. After step 8 of the current algorithm, which sets the cookie’s "secure-only-flag", execute the following step:

   1. If the "scheme" component of the "request-uri" does not denote a "secure" protocol (as defined by the user agent),
and the cookie’s "secure-only-flag" is "true", then abort these steps and ignore the newly created cookie entirely.

2. Before step 11, execute the following step:

   1. If the newly created cookie’s "secure-only-flag" is not set, and the "scheme" component of the "request-uri" does not denote a "secure" protocol, then abort these steps and ignore the newly created cookie entirely if the cookie store contains one or more cookies that meet all of the following criteria:

      1. Their "name" matches the "name" of the newly created cookie.

      2. Their "secure-only-flag" is set.

      3. Their "domain" domain-matches the "domain" of the newly created cookie, or vice-versa.

      Note: This comparison intentionally ignores the "path" component. The intent is to allow the "secure" flag to supercede the "path" restrictions to protect sites against cookie fixing attacks.

      Note: This allows "secure" pages to override "secure" cookies with non-secure variants. Perhaps we should restrict that as well?

3. Adjust the eviction priority order at the bottom of Section 5.3 to be the following:

   1. Expired cookies.

   2. Cookies whose "secure-only-flag" is not set and which share a "domain" field with more than a predetermined number of other cookies.

   3. Cookies that share a "domain" field with more than a predetermined number of other cookies.

   4. All cookies.

   Note: This means that we’d remove every non-secure cookie for an origin before removing any non-expired secure cookie. That seems like a good reason for sites to prefer the "secure" flag.
4. Security Considerations

This specification increases a site’s confidence that secure cookies it sets will remain unmodified by insecure pages on hosts which it domain-matches. Ideally, sites would use HSTS as described in [RFC6797] to defend more robustly against the dangers of non-secure transport in general, but until adoption of that protection becomes ubiquitous, this deprecation this document recommends will mitigate a number of risks.
