NVO3 Operational Requirements draft-ashwood-nvo3-operational-requirement-01

Abstract

This document provides framework and requirements for Network Virtualization over Layer 3 (NVO3) Operations, Administration, and Maintenance (OAM). This document for the most part gathers requirements from existing IETF drafts and RFCs which have already extensively studied this subject for different data planes and layering. As a result this draft is high level and broad. We begin to ask which are truly required for NVO3 and expect the list to be narrowed by the working group as subsequent versions of this draft are created.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 12, 2013.

Internet-Draft	NV03 Op	erational	Requirements	November	2012
Authors' Addre	sses			 	. 15

1. Introduction

This document provides framework and requirements for Network virtualization over Layer 3(NVO3) Operation, Administration, and Maintenance (OAM). Given that this OAM subject is far from new and has been under extensive investigation by various IETF working groups (and several other standards bodies) for many years, this document draws from existing work, starting with [RFC6136]. As a result, sections of [RFC6136] have been reused with minor changes with the permission of the authors.

NVO3 OAM requirements are expected to be a subset of IETF/IEEE etc. work done so far; however, we begin with a full set of requirements and expect to prune them through several iterations of this document.

1.1. OSI Definitions of OAM

The scope of OAM for any service and/or transport/network infrastructure technologies can be very broad in nature. OSI has defined the following five generic functional areas commonly abbreviated as "FCAPS" [NM-Standards]:

- o Fault Management,
- o Configuration Management,
- o Accounting Management,
- o Performance Management, and
- o Security Management.

This document focuses on the Fault, Performance and to a limited extent the Configuration Management aspects. Other functional aspects of FCAPS and their relevance (or not) to NVO3 are for further study.

Fault Management can typically be viewed in terms of the following categories:

- o Fault Detection
- o Fault Verification
- o Fault Isolation
- o Fault Notification and Alarm Suppression

o Fault Recovery

Fault detection deals with mechanism(s) that can detect both hard failures such as link and device failures, and soft failures, such as software failure, memory corruption, misconfiguration, etc.Fault detection relies upon a set of mechanisms that first allow the observation of an event, then the use of a protocol to dynamically notify a network/system operator (or management system) about the event occurrence, then diagnosis tools to assess the nature and the gravity of the fault. After verifying that a fault has occurred along the data path, it is important to be able to isolate the fault to the level of a given device or link. Therefore, a fault isolation mechanism is needed in Fault Management. A fault notification mechanism should be used in conjunction with a fault detection mechanism to notify the devices upstream and downstream to the fault detection point. The fault notification mechanism should also notify NMS systems. For example, when there is a client/server relationship between two layered networks (for example the NVO3 layer would be a client of the outer IP server layer) while the inner IP layer would be a client of the NVO3 server layer 2); fault detection at the server layer may result in the following fault notifications:

- o Sending a forward fault notification from the server layer to the client layer network(s) using the fault notification format appropriate to the client layer.
- o Sending a backward fault notification at the server layer, if applicable, in the reverse direction.
- o Sending a backward fault notification at the client layer, if applicable, in the reverse direction.

Finally, fault recovery deals with recovering from the detected failure by switching to an alternate available data path (depending on the nature of the fault) using alternate devices or links. Note, given that the IP network on which NVO3 resides is usually self healing, it is expected that recovery would not normally be required by the NVO3 layer. The special case of a static IP overlay network, or possibly a centrally controlled IP overlay network may however require NVO3 involvement in fault recovery.

Performance Management deals with mechanism(s) that allow determining and measuring the performance of the network/services under consideration. Performance Management can be used to verify the compliance to both the service-level and network-level metric objectives/specifications. Performance Management typically consists of measuring performance metrics, e.g., Frame Loss, Frame Delay, Frame Delay Variation (aka Jitter), etc., across managed entities

[Page 5]

when the managed entities are in available state. Performance Management is suspended across unavailable managed entities.

1.2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

1.3. Relationship with Other OAM Work

This document leverages requirements that originate with other OAM work, specifically the following:

- o [RFC6136] provides a template and some of the high level requirements and introductory wording.
- o [IEEE802.1ag] is expected to provide a subset of the requirements for NVO3 both at the Tenant level and also within the L3 Overlay network.
- o [Y.1731] is expected to provide a subset of the requirements for NVO3 at the Tenant level.
- o Section 3.8 of [NVO3-DP-Regs] lists several requirements specifically concerning ECMP/LAG.

2. Terminology

The terminology defined in [NVO3-framework] and [NVO3-DP-Regs] is used throughout this document. We introduce no new terminology.

3. NVO3 Reference Model

Figure 1 below reproduces the generic NVO3 reference model as per [NVO3-framework].

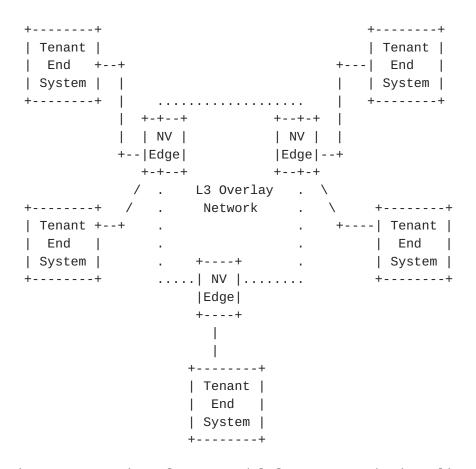

Figure 1: Generic reference model for DC network virtualization over a Layer3 infrastructure

Figure 2 below, reproduces the Generic reference model for the NV Edge (NVE) as per [NV03-DP-Reqs].

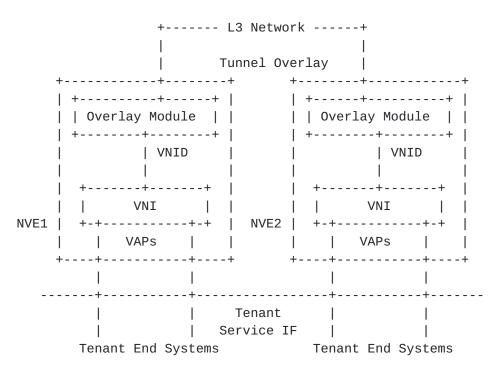

Figure 2: Generic reference model for NV Edge

4. OAM Framework for NVO3

Figure 1 showed the generic reference model for a DC network virtualization over an L3 (or L3VPN) infrastructure while Figure 2 showed the generic reference model for the Network Virtualization (NV) Edge.

L3 network(s) or L3 VPN networks (either IPv6 or IPv4, or a combination thereof), provide transport for an emulated layer 2 created by NV Edge devices. Unicast and multicast tunneling methods (de-multiplexed by Virtual Network Identifier (VNID)) are used to provide connectivity between the NV Edge devices. The NV Edge devices then present an emulated layer 2 network to the Tenant End Systems at a Virtual Network Interface (VNI) through Virtual Access Points (VAPs). The NV Edge devices map layer 2 unicast to layer 3 unicast point-to-point tunnels and may either map layer 2 multicast to layer 3 multicast tunnels or may replicate packets onto multiple layer 3 unicast tunnels.

4.1. OAM Layering

The emulated layer 2 network is provided by the NV Edge devices to which the Tenant End Systems are connected. This network of NV Edges can be operated by a single service provider or can span across multiple administrative domains. Likewise, the L3 Overlay Network

can be operated by a single service provider or span across multiple administrative domains.

While each of the layers is responsible for its own OAM, each layer may consist of several different administrative domains. Figure 3 shows an example.

OAM - - -TENANT |-----| TENANT {all IP/ETH} NV Edge |-----| NV Edge {t.b.d.} IP(VPN) |---| IP(VPN) |---| IP(VPN) {IP(VPN)/ETH}

Figure 3: OAM layers in an NVO3 network

For example, at the bottom, at the L3 IP overlay network layer IP(VPN) and/or Ethernet OAM mechanisms are used to probe link by link, node to node etc. OAM addressing here means physical node loopback or interface addresses.

Further up, at the NV Edge layer, NVO3 OAM messages are used to probe the NV Edge to NV Edge tunnels and NV Edge entity status. OAM addressing here likely means the physical node loopback together with the VNI (to de-multiplex the tunnels).

Finally, at the Tenant layer, the IP and/or Ethernet OAM mechanisms are again used but here they are operating over the logical L2/L3 provided by the NV-Edge through the VAP. OAM addressing at this layer deals with the logical interfaces on Vswitches and Virtual Machines.

4.2. OAM Domains

Complex OAM relationships exist as a result of the hierarchical layering of responsibility and of breaking up of end-to-end responsibility.

The OAM domain above NVO3, is expected to be supported by existing IP and L2 OAM methods and tools.

The OAM domain below NVO3, is expected to be supported by existing IP/L2 and MPLS OAM methods and tools. Where this layer is actually multiple domains spliced together, the existing methods to deal with these boundaries are unchanged. Note however that exposing LAG/ECMP detailed behavior may result in additional requirements to this

domain, the deatils of which will be specified in the future versions of this draft.

When we refer to an OAM domain in this document, or just 'domain', we therefore refer to a closed set of NV Edges and the tunnels which interconnect them. Inter-domain OAM considersations will be specified in the future versions of this draft

5. NVO3 OAM Requirements

The following numbered requirements originate from [RFC6136]. All are included however where they seem obviously not relevant (to the present authors) an explanation as to why is included.

5.1. Discovery

R1) NVO3 OAM MUST allow an NV Edge device to dynamically discover other NV Edge devices that share the same VNI within a given NVO3 domain.

5.2. Connectivity Fault Management

5.2.1. Connectivity Fault Detection

- R2) NVO3 OAM MUST allow proactive connectivity monitoring between two NV Edge devices that support the same VNIs within a given NV03 domain.
- R3) NVO3 OAM MUST allow monitoring/tracing of all possible paths between NV Edge devices. Using this feature, equal cost paths that traverse LAG and/or ECMP may be differentiated.

5.2.2. Connectivity Fault Verification

R4) NVO3 OAM MUST allow connectivity fault verification between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.2.3. Connectivity Fault localization

R5) NVO3 OAM MUST allow connectivity fault localization between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.2.4. Connectivity Fault Notification and Alarm Suppression

R6) NVO3 OAM MUST support fault notification to be triggered as a result of the faults occured at the underneath network infrastructure. This fault notification SHOULD be used for the

suppression of redundant service-level alarms.

5.3. Frame Loss

R7) NVO3 OAM MUST support measurement of per VNI frame/packet loss between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.4. Frame Delay

- R8) NVO3 OAM MUST support measurement of per VNI two-way frame/packet delay between two NV edge devices that support the same VNI within a given NVO3 domain.
- R9) NVO3 OAM MUST support measurement of per VNI one-way frame/packet delay between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.5. Frame Delay Variation

R10) NVO3 OAM MUST support measurement of per VNI frame/packet delay variation between two NV Edge devices that support the same VNI within a given NVO3 domain.

5.6. Availability

A service may be considered unavailable if the service frames/packets do not reach their intended destination (e.g., connectivity is down) or the service is degraded (e.g., frame/packet loss and/or frame/packet delay and/or delay variation threshold is exceeded). Entry and exit conditions may be defined for the unavailable state. Availability itself may be defined in the context of a service type. Since availability measurement may be associated with connectivity, frame/packet loss, frame/packet delay, and frame/packet delay variation measurements, no additional requirements are specified currently.

<u>5.7</u>. Data Path Forwarding

- R11) NVO3 OAM frames MUST be forwarded along the same path (i.e., links (including LAG members) and nodes) as the NVO3 data frames.
- R12) NVO3 OAM frames MUST provide a mechanism to exercise/trace all data paths that result due to ECMP/LAG hops.

5.8. Scalability

R13) NVO3 OAM MUST be scalable such that an NV edge device can support proactive OAM for each VNI that is supported by the device. (Note - Likely very hard to achieve with hash based ECMP/LAG).

5.9. Extensibility

R14) NVO3 OAM MUST be extensible such that new functionality and information elements related to this functionality can be introduced in the future.

R15) NVO3 OAM MUST be defined such that devices not supporting the OAM are able to forward the OAM frames in a similar fashion as the regular NVO3 data frames/packets.

5.10. Security

R16) NVO3 OAM frames MUST be prevented from leaking outside their NV03 domain.

R17) NVO3 OAM frames from outside an NVO3 domain MUST be prevented from entering the said NVO3 domain when such OAM frames belong to the same level or to a lower-level OAM. (Trivially met because hierarchical domains are independent technologies.)

R18) NVO3 OAM frames from outside an NVO3 domain MUST be transported transparently inside the NVO3 domain when such OAM frames belong to a higher-level NVO3 domain. (Trivially met because hierarchical domains are independent technologies).

5.11. Transport Independence

Similar to transport requirement from [RFC6136], we expect NVO3 OAM will leverage the OAM capabilities of the transport layer (e.g., IP underlay).

R19) NVO3 OAM MAY allow adaptation/interworking with its IP underlay OAM functions. For example, this would be useful to allow fault notifications from the IP layer to be sent to the NVO3 layer and likewise exposure of LAG / ECMP will require such non-independence.

5.12. Application Independence

R20) NVO3 OAM MUST be independent of the application technologies and specific application OAM capabilities.

6. Items for Further Discussion

This section identifies a set of operational items which may be elaborated further if these items fail within the scope of the NVO3.

- o VNID renumbering support
 - * Means to change the VNID assigned to a given instance MUST be supported.
 - * VNID renumbering MUST NOT alter the service availability.
 - * A VNE MUST be able to map a VNID with a virtual network context.
- o VNI migration and management operations
 - * Means to delete an existing VNI MUST be supported.
 - * Means to add a new VNI MUST be supported.
 - * Means to merge several VNIs SHOULD be supported.
 - * Means to retrieve reporting data per VNI MUST be supported.
 - * Means to monitor the network resources per VNI MUST be supported.
- o Support of planned maintenance operations on the NVO3 infrastructure
 - * Graceful procedure to allow for planned maintenance operation on NVE MUST be supported.
- o Inter-VNI communication support
 - * For global reachability purposes, inter-VNI communication MUST be supported. This can be enforced using a NAT function.
- o Activation of new network-related services to the NVO3
 - * Means to assist in activating new network services (e.g., multicast) without impacting running service should be supported.
- o Inter-operator NVO3 considerations

- * As NVO3 may be deployed over inter-operator infrastructure, coordinating OAM actions in each individual domain are required to ensure an e2e OAM. In particular, this assumes existence of agreements on the measurement and monitoring methods, fault detection and repair actions, extending QoS classes (e.g., DSCP mapping policies), etc.
 - + [[DISCUSSION NOTE: Should inter-operator issues be declared out of scope?]]

7. IANA Considerations

This memo includes no request to IANA.

8. Security Considerations
