Map-like data in CBOR and CDDL

Abstract

The Concise Binary Object Representation (CBOR, RFC 8949) is a data format whose design goals include the possibility of extremely small code size, fairly small message size, and extensibility without the need for version negotiation.

Basic CBOR supports unordered maps free of duplicate keys, similar to the way JSON defines JSON objects (RFC 8259). Using the CBOR extension point of tags, tags for a selection of variants of maps and multimaps have been registered, but gaps remain. The present document defines a consolidated set of CBOR tags for map-like data items involving key-value pairs.

The Concise Data Definition Language (CDDL), standardized in RFC 8610, is often used to express CBOR data structure specifications. It provides "control operators" as its main language extension point.

The present document defines a number of control operators that enable the description of CBOR data structures that make use of the newly defined tags or that employ the same underlying structures.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents

at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 6 October 2021.

1. Introduction

(See abstract for now.)

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

This specification uses terminology from [[RFC8949](#)] and [[RFC8610](#)]. In particular, with respect to CDDL control operators, "target" refers to the left hand side operand, and "controller" to the right hand side operand. The terms "array" and "map" (if unadorned) refer to CBOR major type 4 and CBOR major type 5; this is not called out explicitly.

2. CBOR tags for map-like data items

This document defines a consolidated set of CBOR tags for map-like entities involving key-value pairs. These tags encode the following meta-data concerning map-like data items:

- *the homogeneity of the key and value types,
- *whether the order of the key-value pairs carries semantic value ("ordered") or needs to be ignored ("unordered"),
- *the uniqueness of the keys, and,
- *the major type used to encode the key-value pairs.

Note that the term "ordered" as used in this document is distinct from "sorted" -- "ordered" implies that the order in the data item interchanged conveys a semantically relevant ordering, while a property "sorted" can easily be established after interchange (by, simply, sorting), less often needs to be indicated, and is more complex to indicate as it may need details about the sorting

2.1. Summary

Tag	LSBs	Homogeneous Value	Homogeneous Key	Ordering	Duplicate Keys Allowed	Data Item	Related Tag
128	0000	No	No	Unordered	No	map	259
129	0001	No	No	Unordered	Yes	array	TDB280*
130	0010	No	No	Ordered	No	array	TBD279*
131	0011	No	No	Ordered	Yes	array	
132	0100	No	Yes	Unordered	No	map	275
133	0101	No	Yes	Unordered	Yes	array	
134	0110	No	Yes	Ordered	No	array	
135	0111	No	Yes	Ordered	Yes	array	
136	1000	Yes	Yes	Unordered	No	map	
137	1001	Yes	Yes	Unordered	Yes	array	
138	1010	Yes	Yes	Ordered	No	array	
139	1011	Yes	Yes	Ordered	Yes	array	

Table 1: New CBOR tags defined in this document

*TBD279: https://github.com/Seikenre/cbor-ordered-map-spec/blob/master/CBOR_Ordered_Map.md

*TBD280: <https://github.com/ecorm/cbor-tag-multimap>

[The intention of the present document is to obviate the need for defining TBD279/TBD280.]

[Appendix A.1](#) provides information about constructs in a few programming languages that are related to the tags being defined.

2.2. Key/Value Type

Bits 2/3 of the tag provides information on the map's key and value types:

*0b00xx Unspecified: There is no specified type for the map's keys and values

*0b01xx Homogeneous Key: All keys have the same data type

*0b10xx Homogeneous Key/Value: All values have the same data type in addition to all keys having the same data type (the types for keys and values may be distinct).

The semantics for homogeneity shall be the same as for RFC8746 homogeneous arrays (tag 41). That is, "which CBOR data items constitute elements of the same application type is specific to the application" (RFC8746, subsection 3.2).

Maps with arbitrary keys and homogeneous values are considered unusual, so they are left out of this specification in order to reduce the number of tags allocated (12 instead of 16).

2.3. Ordering

Bit 1 of the tag represents the map's ordering semantics:

*0: The order of key-value pairs is unspecified

*1: Key-value pairs are encoded in the same order in which they were inserted

2.4. Key Uniqueness

Bit 0 of the tag represents the uniqueness of the map's keys.

*0: Keys are unique

*1: Keys may be duplicated (i.e. multimaps)

2.5. Data Item

All these map-like data items could be represented as a tag with an enclosed array of alternating key-value pairs, as in:

```
129(["key1", 1, "key2", 2])
```

However, representing the key-value pairs as a CBOR map for those cases where this is possible enables generic decoders that are oblivious of these tags to represent the data in a more appropriate platform type.

Specifically, the key-value pairs are represented as a map if and only if

*the ordering is unspecified and

*the keys are unique;

they are represented as an array of alternating keys and values otherwise.

2.6. Related Tags (Informative)

2.6.1. Tag 259

Specification: <https://github.com/shanewholloway/js-cbor-codec/blob/master/docs/CBOR-259-spec--explicit-maps.md>

The above defined tag 128 may be used instead to guide a JavaScript decoder into interpreting a CBOR map as a JavaScript Map instead of an Object.

2.6.2. Tag 275

Specification: <https://github.com/ecorm/cbor-tag-text-key-map>

The above defined tag 132 may be used instead to guide a decoder into interpreting a CBOR map as a JavaScript-like Object having only text string keys. The decoder would have to verify the first key to establish that the map has homogeneous text string keys.

2.6.3. Tag TBD279

Draft specification: https://github.com/Seckenre/cbor-ordered-map-spec/blob/master/CBOR_Ordered_Map.md

The above defined tag 130 may be used instead to encode map-like data items where the order of the key-value pairs is semantically significant.

2.6.4. Tag TDB280

Draft specification: <https://github.com/ecorm/cbor-tag-multimap>

The above defined tag 129 may be used instead to encode a multimap as an array of key-value pairs.

3. CDDL Support for Map-Like Data Items

The Concise Data Definition Language (CDDL), standardized in RFC 8610, provides "control operators" as its main language extension point.

The present document defines a number of control operators that enable the use of group notation (enclosed in a CDDL map) to specify any of the above map-like data structures:

Name	Purpose
.omm	Ordered (Multi-)Map
.umm	Unordered (Multi-)Map
.unique	Uniqueness requirement

Table 2: New control operators
in this document

3.1. Map notation for map-like data items

[needs better examples]

CDDL already can describe both arrays of alternating keys and values and maps (unordered and with unique keys). The two control operators `.omm` and `.umm` introduced in this section enable the use of CDDL map notation for map-like types beyond actual maps, increasing readability and possibly even reusability.

In a simple example that provides an unordered collection of zero or more home addresses and zero or more work addresses, each labeled as such, we use traditional map notation to describe that collection:

```
[* (text, any)] .umm {  
  * home: address  
  * work: address  
  $$more-addresses  
}
```

The `.omm` and `.umm` control operators convert a group definition enclosed into a CDDL map given as a controller type into an array type given as the target type. The controller type given is unwrapped ([Section 3.7](#) of [\[RFC8610\]](#)) into a group. Keys and values of the entries in that group are then alternately matched as elements in the target array. Note that both target and controller type can contribute to the shaping of the data; declaring the key type as `text` limits what can be added to the `$$more-addresses` socket.

`.omm` and `.umm` differ in the semantics of the array type created: `.omm` defines an ordered (multi)map, i.e., the order of the key/value element pairs in the array matters, while `.umm` defines an unordered (multi)map, i.e., data items that present the same set of key/value pairs in different orders are equivalent.

Note that the ability to specify specific ("homogeneous") types is provided by the ability to specify the target type, as in the example above.

Note that there is not strictly a need to define a control operator for building unordered maps with non-duplicate keys, as existing CBOR maps already fill this role, however the use of a map type as the target is allowed for symmetry (implying uniqueness of the keys), allowing the following:

```
{* text => any} .umm {  
  ? home: address  
  ? work: address  
  $$more-addresses  
}
```

3.2. Uniqueness

The `.unique` control annotates the target as requiring uniqueness, within the enclosing container(*), of its value, among the other data items in that enclosing container that are also marked `.unique`, with the same controller.

E.g.,

```
feature-set = [* feature .unique "set"]  
ordered-pairs-with-unique-keys-and-values =  
  [* (any .unique "key", any .unique "value") ]
```

defines a `feature-set` as an array of zero or more feature values that need to be all different (as they are unique in set), and `ordered-map-with-unique-keys-and-values` as an array of zero pairs of keys and values, where the keys need to be unique among themselves and the values need to be unique among themselves (the latter example could employ an `.omm` or `.umm` operator to further restrict what can be in these keys and values).

Discussion: (*) while it is probably not a big problem to define what exactly the "enclosing" container is, it may be useful to actually define a larger scope of the uniqueness. CDDL currently does not have a way to establish and point to such a larger scope; we might define one ad hoc here or leave that for later extension.

4. CDDL typenames

For the use with CDDL [RFC8610], the typenames defined in [Figure 1](#) are recommended unless there is a need for more specific shaping of the data.

```

anymap = {* any => any}

tbd128 = #6.128(anymap)
tbd129 = #6.129([* (any, any)] .umm anymap)
tbd130 = #6.130([* ((any .unique "mm"), any)] .omm anymap)
tbd131 = #6.131([* (any, any)] .omm anymap)
tbd132<k> = #6.132({* k => any})
tbd133<k> = #6.133([* (k, any)] .umm anymap)
tbd134<k> = #6.134([* ((k .unique "mm"), any)] .omm anymap)
tbd135<k> = #6.135([* (k, any)] .omm anymap)
tbd136<k,v> = #6.136({* k => v})
tbd137<k,v> = #6.137([* (k, v)] .umm anymap)
tbd139<k,v> = #6.138([* ((k .unique "mm"), v)] .omm anymap)
tbd139<k,v> = #6.139([* (k, v)] .omm anymap)

```

Figure 1: Recommended typenames for CDDL

[fill in better names for tbdnnn]

Note that there is no need to call out the uniqueness of the keys explicitly in tbd128, tbd132, or tbd136, as the use of maps as a representation format already provides that key uniqueness.

5. IANA Considerations

5.1. Tags

IANA is requested to allocate the tags of [Table 1](#) in the CBOR tags registry [[IANA.cbor-tags](#)], using this document as the specification reference.

The allocations are requested to be assigned from the "specification required" space (24..255).

5.2. CDDL control operators

This document requests IANA to register the contents of [Table 3](#) into the CDDL Control Operators registry [[IANA.cddl](#)]:

Name	Reference
.omm	[RFCthis]
.umm	[RFCthis]
.unique	[RFCthis]

Table 3

6. Implementation Status

TBD

7. Security considerations

The security considerations of [RFC8610] apply.

Appendix A. Implementation Considerations

This non-normative appendix provides information about the use on implementations of the tags and control operators defined.

A.1. Programming Language Containers (Informative)

The following subsections describe how the tags in this document relate to various programming language containers. Containers that are not part of the programming language or its standard libraries are not considered here.

The *Encoding Tag* column in the following tables provide the recommended tag that best represents the given container type. For example, it's possible to use tag 132 for encoding an ECMAScript Map if all keys happen to be of the same type, however tag 128 is more general and applies to any Map. When encoding an ECMAScript Object,

tag 128 would be technically correct but is too general; tag 132 best presents the fact that an Object has text keys only.

The *Decodable Tags* column in the following tables, are for data items can be decoded into the destination container without having to inspect the following:

- *the uniqueness of the keys,
- *the ordering of the keys, and,
- *the data types of **every** keys/value pair.

It may however be necessary to inspect the data types of the **first** key-value pair in the case of tags representing homogeneous keys/values.

A.1.1. ECMAScript

Container	Encoding Tag	Decodable Tags
Object	132	132, 136
Map	128	128, 132, 136
Array of pairs	131	All

Table 4

A.1.2. Python

Container	Encoding Tag	Decodable Tags
TypedDict	136	136
namedtuple	132	132, 136
dict	128	128, 132, 136
OrderedDict	130	130, 134, 138
list of 2-tuples	131	All

Table 5

A.1.3. C++

Container(s)	Encoding Tag	Decodable Tags
Map<K, T>	136	136
Map<K, D>	132	132, 136
Map<D, D>	128	128, 132, 136
MultiMap<K, T>	137	137
MultiMap<K, D>	133	133
MultiMap<D, D>	129	128, 129
Sequence<Pair<K, T>>	139	[136, 139]
Sequence<Pair<K, D>>	135	[132, 139]
Sequence<Pair<D, D>>	131	All

Table 6

Legend:

*K: Static key type

*T: Static value type

*D: Suitable dynamic type, such as `std::any` or `std::variant`

*Map: `std::map` or `std::unordered_map`

*MultiMap: `std::multimap` or `std::unordered_multimap`

*Sequence: Sequence container that maintains order (e.g. `std::vector`)

*Pair: Object containing a key and a value, such as `std::pair`, or `std::tuple`.

Note that a C++ `std::map` stores its key-value pairs in a sorted fashion, and does **not** preserve insertion order in the same manner as Python's `OrderedDict`.

A.2. CDDL Implementation Considerations

TBD

Acknowledgements

The CBOR tags defined in this document were developed by Emile Cormier under the sponsorship of Duc Luong, based on discussions with Kio Smallwood and Joe Hildebrand. The CDDL control operators defined in this document were developed by Carsten Bormann, Brendan Moran, and Henk Birkholz.
