CoRE Working Group Internet-Draft Intended status: Standards Track Expires: May 29, 2016

Block-wise transfers in CoAP: Extension for Reliable Transport (BERT) draft-bormann-core-block-bert-00

Abstract

CoAP (<u>RFC7252</u>) is a RESTful transfer protocol for constrained nodes and networks, originally using UDP or DTLS over UDP as its transport. Basic CoAP messages work well for the small payloads we expect from temperature sensors, light switches, and similar building-automation devices. CoAP's Block protocol (<u>draft-ietf-core-block</u>) allows transferring larger payloads over limited-size datagrams -- for instance, for firmware updates.

CoAP over TCP and TLS (<u>draft-ietf-core-tcp-tls</u>) enables the use of extended, but not unlimited, size messages. The present specification, Block-wise transfers in CoAP: Extension for Reliable Transport (BERT), extends the block protocol in a simple way to be able to make use of these larger messages over a reliable transport.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of <u>BCP 78</u> and <u>BCP 79</u>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <u>http://datatracker.ietf.org/drafts/current/</u>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 29, 2016.

1. Introduction

(see abstract for now)

<u>1.1</u>. Objectives

The objectives stated in the introduction of [I-D.ietf-core-block] apply to the present document as well. (The exception is the desire to enable individual retransmissions -- this is already handled by reliable transport.)

Specifically, this specification continues to minimize the need for creation of additional state, even if a TCP (or TLS over TCP) connection already requires more state than a basic CoAP client-to-server relationship.

An important aspect of this also is the need for state at proxies, see <u>Section 2.1</u>.

[Page 2]

CoAP-BERT

<u>1.2</u>. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>RFC</u> <u>2119</u>, <u>BCP 14</u> [<u>RFC2119</u>] and indicate requirement levels for compliant implementations.

In this document, the term "byte" is used in its now customary sense as a synonym for "octet".

Where bit arithmetic is explained, this document uses the notation familiar from the programming language C, except that the operator "**" stands for exponentiation.

BERT Option:

A Block1 or Block2 option that includes an SZX value of 7.

BERT Block:

The payload of a CoAP message that is affected by a BERT Option in descriptive usage (Section 2.1 of [<u>I-D.ietf-core-block</u>]).

2. BERT Blocks

The use of the present extension is signalled by sending Block1 or Block2 options with SZX == 7 (a "BERT option"). (SZX == 7 is a value that was reserved in [I-D.ietf-core-block].)

In control usage, a BERT option is interpreted in the same way as the equivalent option with SZX == 6, except that it also indicates the capability to process BERT blocks. As with the basic Block protocol, the recipient of a CoAP request with a BERT option in control usage is allowed to respond with a different SZX value, e.g. to send a non-BERT block instead.

In descriptive usage, a BERT option is interpreted in the same way as the equivalent option with SZX == 6, except that the payload is allowed to contain a multiple of 1024 bytes (non-final BERT block) or more than 1024 bytes (final BERT block).

The recipient of a non-final BERT block (M=1) conceptually partitions the payload into a sequence of 1024-byte blocks and acts exactly as if it had received this sequence in conjunction with block numbers starting at, and sequentially increasing from, the block number given in the Block option. In other words, the entire BERT block is positioned at the byte position that results from multiplying the block number with 1024. The position of further blocks to be transferred is indicated by incrementing the block number by the

[Page 3]

number of elements in this sequence (i.e., the size of the payload divided by 1024 bytes).

As with SZX == 6, the recipient of a final BERT block (M=0) simply appends the payload at the byte position that is indicated by the block number multiplied with 1024.

<u>2.1</u>. Caching Considerations

Section 2.10 of [I-D.ietf-core-block] applies unchanged.

Discussion: As with the basic Block protocol, a proxy may need to reslice blocks. Requiring BERT blocks to start at 1024 byte boundaries simplifies this considerably.

2.2. Open Questions

Does the use of CoAP over TCP or TLS simply imply BERT capability or do we explicitly signal that? Signalling is easy for Block2 (but does require sending Block2 options with the value 7 as a matter of course), less so for Block1.

If an optimistic approach is desired, the error code 4.13 (Request Entity Too Large) could be employed as defined in Section 2.5 of [I-D.ietf-core-block].

2.3. Combining BERT blocks with the Observe Option

BERT Blocks combine with the Observe Option exactly as defined for basic blocks in Section 2.6 of [<u>I-D.ietf-core-block</u>].

3. Examples

This section extends Section 3 of [I-D.ietf-core-block] with a few examples that involve BERT options. Extending the notation used in that section, a value of SZX == 7 is shown as "BERT", or as "BERT(nnn)" to indicate a payload of size nnn.

In all these examples, a Block option is shown in a decomposed way indicating the kind of Block option (1 or 2) followed by a colon, and then the block number (NUM), more bit (M), and block size exponent $(2^{**}(SZX+4))$ separated by slashes. E.g., a Block2 Option value of 33 would be shown as 2:2/0/32), or a Block1 Option value of 59 would be shown as 1:3/1/128.

Internet-Draft

COAP-BERT

<u>3.1</u>. Block2 Example

The first example (Figure 1) shows a GET request with a response that is split into three BERT blocks. The first response contains 3072 bytes of payload; the second, 5120; and the third, 4711. Note how the block number increments to move the position inside the response body forward.

CLIENT	SERVER
GET, /status	>
<pre> < 2.05 Content, 2:0/1/BERT(</pre>	3072)
GET, /status, 2:3/0/BERT	>
< 2.05 Content, 2:3/1/BERT(5120)
GET, /status, 2:8/0/BERT -	>
<pre> < 2.05 Content, 2:8/0/BERT(</pre>	4711)

Figure 1: GET with BERT blocks

3.2. Block1 Example

The following example (Figure 2) demonstrates a PUT exchange with BERT blocks.

```
CLIENT
                                         SERVER
 | PUT, /options, 1:0/1/BERT(8192) -----> |
 | <----- 2.31 Continue, 1:0/1/BERT</pre>
| PUT, /options, 1:8/1/BERT(16384) -----> |
 <----- 2.31 Continue, 1:8/1/BERT</pre>
                                           | PUT, /options, 1:24/0/BERT(5683) -----> |
 <----- 2.04 Changed, 1:24/0/BERT</pre>
                                           Т
```

4. IANA Considerations

This specification makes no requests of IANA.

(This section to be removed by the RFC editor.)

<u>5</u>. Security Considerations

The Security Considerations of [<u>I-D.ietf-core-block</u>] apply unchanged.
