**Flooding Topology Computation Algorithm**  
**draft-cc-lsr-flooding-reduction-07**

Abstract

This document proposes an algorithm for a node to compute a flooding topology, which is a subgraph of the complete topology per underline physical network. When every node in an area automatically calculates a flooding topology by using a same algorithm and floods the link states using the flooding topology, the amount of flooding traffic in the network is greatly reduced. This would reduce convergence time with a more stable and optimized routing environment.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 19, 2020.

## [1.](#) Introduction

For some networks such as dense Data Center (DC) networks, the existing Link State (LS) flooding mechanism is not efficient and may have some issues. The extra LS flooding consumes network bandwidth. Processing the extra LS flooding, including receiving, buffering and decoding the extra LSs, wastes memory space and processor time. This

may cause scalability issues and affect the network convergence negatively.

This document proposes an algorithm for a node to compute a flooding topology, which is a subgraph of the complete topology per underline physical network. When every node in an area automatically calculates a flooding topology by using a same algorithm and floods the link states using the flooding topology, the amount of flooding traffic in the network is greatly reduced. This would reduce convergence time with a more stable and optimized routing environment.

There may be multiple algorithms for computing a flooding topology. Users can select one they prefer, and smoothly switch from one to another.

## **2. Terminology**

LSA: A Link State Advertisement in OSPF.

LSP: A Link State Protocol Data Unit (PDU) in IS-IS.

LS: A Link Sate, which is an LSA or LSP.

FT: Flooding Topology.

FTC: Flooding Topology Computation.

## **3. Flooding Topology**

For a given network topology, a flooding topology is a sub-graph or sub-network of the given network topology that has the same reachability to every node as the given network topology. Thus all the nodes in the given network topology MUST be in the flooding topology. All the nodes MUST be inter-connected directly or indirectly. As a result, LS flooding will in most cases occur only on the flooding topology, that includes all nodes but a subset of links. Note even though the flooding topology is a sub-graph of the original topology, any single LS MUST still be disseminated in the entire network.

### **3.1. Flooding Topology Construction**

Many different flooding topologies can be constructed for a given network topology. For example, a chain connecting all the nodes in the given network topology is a flooding topology. A circle connecting all the nodes is another flooding topology. A tree connecting all the nodes is a flooding topology. In addition, the

tree plus the connections between some leaves of the tree and branch nodes of the tree is a flooding topology.

The following parameters need to be considered for constructing a flooding topology:

- o Degree: The degree of the flooding topology is the maximum degree among the degrees of the nodes on the flooding topology. The degree of a node on the flooding topology is the number of connections on the flooding topology it has to other nodes.
- o Number of links: The number of links on the flooding topology is a key factor for reducing the amount of LS flooding. In general, the smaller the number of links, the less the amount of LS flooding.
- o Diameter: The diameter of the flooding topology is the shortest distance between the two most distant nodes on the flooding topology. It is a key factor for reducing the network convergence time. The smaller the diameter, the less the convergence time.
- o Redundancy: The redundancy of the flooding topology means a tolerance to the failures of some links and nodes on the flooding topology. If the flooding topology is split by some failures, it is not tolerant to these failures. In general, the larger the number of links on the flooding topology is, the more tolerant the flooding topology to failures.

Note that the flooding topology constructed by a node is dynamic in nature, that means when the base topology (the entire topology graph) changes, the flooding topology (the sub-graph) MUST be re-computed/re-constructed to ensure that any node that is reachable on the base topology MUST also be reachable on the flooding topology.

#### **4. Algorithms to Compute Flooding Topology**

There are many algorithms to compute a flooding topology. A simple and efficient one is briefed, which comprises:

- o Selecting a node R0 with the smallest node ID;
- o Building a tree using R0 as root in breadth first; and then
- o Connecting each node whose degree is one to another node to have a flooding topology.

#### 4.1. Algorithm with Considering Degree

The algorithm is described below. The detailed FT computation by the algorithm is illustrated in [Appendix A](#) through an example.

The algorithm starts from node  $R_0$  as root with a given maximum degree  $MaxD$  such as  $MaxD = 3$ , a candidate queue  $Cq = \{(R_0, D = 0, PHs = \{ \})\}$ , and an empty flooding topology  $FT = \{ \}$ .  $Cq$  contains one element  $(R_0, D = 0, PHs = \{ \})$ , where node  $R_0$  is the root,  $D = 0$  indicates that the Degree ( $D$  for short) of  $R_0$  is 0 (i.e., the number of links on the flooding topology connected to  $R_0$  is 0),  $PHs = \{ \}$  indicates that the Previous Hops ( $PHs$  for short) of  $R_0$  is empty.

1. Finding and removing the first element with node  $A$  in  $Cq$  that is not on  $FT$  and one  $PH$ 's  $D$  in  $PHs < MaxD$ .

If  $A$  is root  $R_0$ , then add the element into  $FT$

otherwise (i.e.,  $A \neq R_0$  with one  $PH$ 's  $D$  in  $PHs < MaxD$ . Assume that  $PH$  is the first one in  $PHs$  whose  $D < MaxD$ ),  $PH$ 's  $D++$ , and add  $A$  with  $D = 1$  and  $PHs = \{PH\}$  into  $FT$ .

Note: if there is no element in  $Cq$  satisfying the conditions, then algorithm may be restarted from  $R_0$ ,  $++MaxD$ ,  $Cq = \{(R_0, D=0, PHs = \{ \})\}$ ,  $FT = \{ \}$ ;

2. If all the nodes are on the  $FT$ , then goto step 4;
3. Suppose that node  $X_i$  ( $i = 1, 2, \dots, n$ ) is connected to node  $A$  and not on  $FT$ , and  $X_1, X_2, \dots, X_n$  are in an increasing order by their IDs (i.e.,  $X_1$ 's ID  $<$   $X_2$ 's ID  $<$  ...  $<$   $X_n$ 's ID). If  $X_i$  is not in  $Cq$ , then add it into the end of  $Cq$  with  $D = 0$  and  $PHs = \{A\}$ ; otherwise (i.e.,  $X_i$  is in  $Cq$ ), add  $A$  into the end of  $X_i$ 's  $PHs$ ; Goto step 1.
4. For each node  $B$  on  $FT$  whose  $D$  is one (from minimum to maximum node ID), find a link  $L$  attached to  $B$  such that  $L$ 's remote node  $R$  has minimum  $D$  and ID, add link  $L$  between  $B$  and  $R$  into  $FT$  and increase  $B$ 's  $D$  and  $R$ 's  $D$  by one. Return  $FT$ .

#### 4.2. Algorithm with Considering Others

There may be some constraints on some nodes in a network. For example, in a spine-and-leaf network, there may be a constraint on the degree of every leaf node on the flooding topology, which is that the degree of every leaf node is not greater than a given number  $ConMaxD$  such as  $ConMaxD = 2$ . For each of the other nodes such as the

spine nodes, there is no such constraint, that is that ConMaxD is a huge number for each of these nodes.

Step 1 of the algorithm described above is updated below to consider this constraint. In addition to checking constraint PH's  $D < \text{MaxD}$ , step 1 checks another constraint PH's  $D < \text{PH's ConMaxD}$ .

1. Finding and removing the first element with node A in Cq that is not on FT and one PH's D in PHS  $< \text{MaxD}$  and PH's  $D < \text{PH's ConMaxD}$ .

If A is root R0, then add the element into FT

otherwise (i.e.,  $A \neq R0$  with one PH's D in PHS  $< \text{MaxD}$  and PH's  $D < \text{PH's ConMaxD}$ . Assume that PH is the first one in PHS whose  $D < \text{MaxD}$  and PH's  $D < \text{PH's ConMaxD}$ ), PH's  $D++$ , and add A with  $D = 1$  and PHS = {PH} into FT.

Note: if there is no element with a node in Cq satisfying the conditions, then algorithm may be restarted from R0,  $++\text{MaxD}$ ,  $\text{Cq} = \{(R0, D=0, \text{PHs} = \{ \})\}$ ,  $\text{FT} = \{ \}$ ;

## 5. Security Considerations

This document does not introduce any new security issue.

## 6. IANA Considerations

Under Registry Name: "IGP Algorithm Type For Computing Flooding Topology" under an existing "Interior Gateway Protocol (IGP) Parameters" IANA registries (refer to [Section 7.3](#). IGP [[I-D.ietf-lsr-dynamic-flooding](#)]), IANA is requested to assign one value of IGP Algorithm Type For Computing Flooding Topology as follows:

+=====+=====+=====+		
Type Value	Type Name	reference
+=====+=====+=====+		
1	Breadth First Minimum Degree Algorithm	This document
+-----+-----+-----+		

## 7. Acknowledgements

## Appendix A. FT Computation Details through Example

This section presents the details on FT computation by the algorithm through an example. The detailed procedure of computing a FT for a network of five nodes with full mesh connections is illustrated. Suppose that the network has five nodes R0, R1, R2, R3 and R4; R0's ID < R1's ID < R2's ID < R3's ID < R4's ID. The algorithm starts with  $C_q = \{(R0, D=0, PH=\{\})\}$ ,  $FT = \{\}$ ,  $MaxD = 3$ .

```

0. // remove the first element containing root R0 from Cq
   Cq = { };
   // add the element into FT
   FT = { (R0,D=0,PHs={ }) }; // root R0 on FT
   // for each Ri connected to R0 (not in Cq), add it to the end of Cq
   Cq = { (R1,D=0,PHs={R0}), (R2,D=0,PHs={R0}), (R3,D=0,PHs={R0}),
          ^^^^^^^^^^^^^^^^^^^^^ (R4,D=0,PHs={R0}) }

```

```

1. //remove first element (R1,D=0,PHs={R0}) from Cq, R0's D=0 < MaxD
   Cq = { (R2,0,{R0}), (R3,0,{R0}), (R4,0,{R0}) };
   // add (R1,1,{R0}) into FT, increase PH R0's D by one
   FT = { (R0,1, { }), (R1,1, {R0}) }; // Link R1--R0 on FT
          ^^^          ^^^^^^^^^^^^^^^^^
   // for Ri connected to R1 (in Cq) not on FT, append R1 to Ri's PHs
   Cq = { (R2,0, {R0,R1}), (R3,0, {R0,R1}), (R4,0,{R0,R1}) }.
          ^^          ^^          ^^

```

The diagram illustrates a hexagonal mesh structure with nodes labeled R0, R1, R2, R3, and R4. The nodes are arranged in a hexagonal pattern. The links between nodes are categorized into three types: solid lines, dashed lines, and lines with double slashes (//). The text "Link on FT" is associated with the solid lines, and "link R2--R0 added to FT" is associated with the dashed lines. The diagram shows a central node R0 connected to R1, R2, and R3. R1 is connected to R2 and R3. R2 is connected to R3. The links between R0 and R1, R1 and R2, and R2 and R3 are solid lines. The links between R0 and R2, R1 and R3, and R2 and R0 are dashed lines. The links between R0 and R3, R1 and R2, and R3 and R1 are lines with double slashes (//).

link R3--R0 added to FT

4. //remove the 1st element (R4,0,{R0,R1,R2,R3}) from Cq,R1's D=1 < MaxD

$$Cq = \{ \}$$

```
// add (R4,1,{R1}) into FT, increase R1's D by one
```

$$FT = \{(R0, 3, \{\}), (R1, 2, \{R0\}), (R2, 1, \{R0\}), (R3, 1, \{R0\}), (R4, 1, \{R1\})\}$$

All nodes are on FT now. In the following, for each node on FT whose  $D = 1$  (from minimum to maximum ID), link  $L$  attached to it and not on FT is found such that  $L$ 's remote node has minimum  $D$  and ID.  $L$  is added into FT.

```
5. // On FT, get node R2 with smallest ID whose D=1
```

$$FT = \{(R0, 3, \{\}), (R1, 2, \{R0\}), (R2, 1, \{R0\}), (R3, 1, \{R0\}), (R4, 1, \{R1\})\}$$

```
// Add link R2--R3 to FT,      ^^^^^^^^^^^^^^^
```

```
// where R2--R3 is not on FT, R3's D=1 is minimum first and then
```

```
// R3's ID is minimum (R3 and R4 tie for D), R2's D++ and R3's D++
```

$$FT = \{(R0, 3, \{\}), (R1, 2, \{R0\}), (R2, 2, \{R0, R3\}), (R3, 2, \{R0\}), (R4, 1, \{R1\})\}$$

**6. // On FT, get node R4 with smallest ID whose D=1**

```

FT = {(R0,3,{ }),(R1,2,{R0}),(R2,2,{R0,R3}),(R3,2,{R0}),(R4,1,{R1})}
// Add link R4--R2 to FT, where
// R4--R2 is not on FT, R2's D=2 is minimum first and then R2's ID is
// minimum (R2 and R3 tie for D), increase R2's D and R4's D by one
FT = {(R0,3,{ }),(R1,2,{R0}),(R2,3,{R0,R3}),(R3,2,{R0}),(R4,2,{R1,R2})}

```

FT is computed, which has Degree of 3 and Diameter of 2.
