Abstract

This document provides a mechanism by which the DHCPv4 servers can provide information about the IPv6-over-IPv4 tunnel endpoint. The IPv4/IPv6 dual stack nodes can use this information to set up a tunnel to the tunnel endpoint to obtain IPv6 connectivity without requiring manual intervention at any of the tunnel endpoints at tunnel establishment time.

## 1. Introduction

In the initial deployment of IPv6, the IPv6 nodes may need to communicate with the other IPv6 nodes via IPv4 tunnel service. The connectivity can be obtained by setting up an IPv6-over-IPv4 tunnel between a client and a tunnel router.

This document defines a new option by which the DHCPv4 [[RFC2131](#)] server can notify the client with the list of endpoints of the possible IPv6-over-IPv4 tunnel defined in [[RFC2893](#)] in an automated manner. Through this mechanism, dual stack users attached to IPv4 only networks can connect its IPv6 connectivity to the endpoints as a tunnel router.

Particularly, this mechanism is useful where the ISP is providing the IPv6 services but is doing it using tunneling over IPv4 to avoid upgrading all their infrastructure to support IPv6 on day one.

Regarding IPv6-over-IPv4 tunnel, the tunnel broker [[RFC3053](#)] architecture has been widely deployed in the dual networks to obtain IPv6 connectivity via tunnel service because of easy configuration on the users. After configuring IPv6-over-IPv4 tunnel between the users and the selected tunnel server, tunnel broker allows user to get access to the 6bone or any other IPv6 network the tunnel server is connected to. In case of no tunnel broker, the proposed mechanism in this document can allow users to obtain the IPv6 connectivity efficiently.

### 1.1 Terminology

The following terms pertaining to tunnel are used in this document as defined in [[RFC2893](#)]

o IPv6-over-IPv4 Tunnel:

The technique of encapsulating IPv6 packets within IPv4 so that they can be carried across IPv4 routing infrastructures. IPv6-over-IPv4 tunnel where the IPv4 tunnel endpoint address is determined by configuration information learned from the DHCP Server on the encapsulating node.

o Tunnel endpoint address:

Destination address of IPv4 encapsulating IPv6 packets. It is an IPv4 address in the TEP Option originated from the DHCP Server.

configured to access. Likewise, a client may receive an option that tunnel services for which no corresponding DHCP option was supplied. Clients will interpret this option in a system-specific manner whose specification is outside the scope of this document.

As described in [[RFC2893](#)], the dual node received TEP option MUST store the tunnel endpoint address and this address is used as destination address for the encapsulating IPv4 header.

Although the dual node obtains available tunnel endpoint address from the DHCP server, it can not receive any IPv6 packets from the tunnel router via IPv6-over-IPv4 tunnel because the tunnel router does not recognize which node is likely to configure its tunnel attached to the tunnel router. As described in [[I-D.nielsen-v6ops-zeroconf-goals](#)] the tunnel protocol proposed in this document MUST allow for one tunnel endpoint to verify the reachability of other tunnel endpoint towards which it intends to send packets. After verifying the reachability between them, IPv6 Router Advertisement messages including address configuration information are reached to the dual node correctly, and the dual node configures its unique IPv6 address by itself in a stateless address autoconfiguration manner [[RFC2461](#)]. The dual node thus is able to forward its IPv6 traffics to the tunnel router learned from the TEP option of DHCP.

One example of the reachability function is shown in [Section 10](#) while specific considerations is beyond scope of this document.

The determination of which packets to tunnel is usually made by routing information on the encapsulator. This is usually done via a routing table, which directs packets based on their destination address using the prefix mask and match technique. For more information, refer to [section 4](#). Configured Tunneling in [[RFC2893](#)].

To increase secure exchange between users and tunnel endpoints, the tunnel broker or any tunnel agent can be used for configuring IPv6-over-IPv4 tunnels including authentication, security association and so on, but it is not scope of this document.

The authenticated DHCP [[RFC3118](#)] can be also used for secure exchange between users and tunnel endpoints.

## **7. Extended Usage**

As stated in Introduction, the tunnel broker is a nice tool for allowing user to get the IPv6 connectivity through IPv6-over-IPv4 tunnel. To configure tunnel between users and tunnel servers, users have to access to the tunnel broker by web registration and then tunnel broker set up tunnel between users and a selected tunnel server. Prior to filling up the form on the tunnel broker, users have to know the IPv4 address of the tunnel broker (as described in [[RFC3053](#)], it may be IPv6 addressable but not mandatory). Regarding this operation, this option proposed in this document can allow users to obtain an available tunnel broker address (or addresses) without any manual operations.

For this operation, a new option (called Tunnel Broker Configuration Option: option name is OPTION\_TBCO and value is TBD) can be simply made by DHCPv4 option extension which may be the same format as TEP option.

To increase secure exchange between users and tunnel endpoints (tunnel servers or dual routers) this extended usage can be applied for configuring IPv6-over-IPv4 tunnel instead of direct tunnel configuration between them. Specific method for secure exchange is beyond scope of this document.

## **8. IANA Considerations**

IANA is requested to an assign value for the IPv6-over-IPv4 Tunnel End Point option code in accordance with [[RFC2939](#)].

Option Name	Value	Described in
OPTION_TEP	TBD	<a href="#">Section 3.</a>
OPTION_TBCO	TBD	<a href="#">Section 7.</a> (if necessary)

## **9. Acknowledgements**

Special thanks to Pekka Savola, Vijayabhaskar A K, Eric Nordmark, Ralph Droms, Bernie Volz and Alain Durand for their many valuable

revisions and comments. In particular, Pekka Savola kindly clarified the multiple tunnel end point considerations with his good experience as well.

Specially, authors would like to acknowledge the implementation contributions by Minhoo Lee of Samsung Electronics.

## **10. Implementation Experiences**

We have implemented TEP option using the Internet Systems Consortium DHCP source code (DHCP-3.0.1-rc13 version) on both DHCP server and client, particularly client is an IPv4/IPv6 dual stack based on Linux operating system.

For the simple implementation, TCP/UDP port assigned both endpoints by operator in advance was used to verify the reachability in this document.
