**IGP Extensions for Segment Routing based Enhanced VPN**  
**draft-dong-lsr-sr-enhanced-vpn-02**

Abstract

Enhanced VPN (VPN+) is an enhancement to VPN services to support the needs of new applications, particularly including the applications that are associated with 5G services. These applications require better isolation and have more stringent performance requirements than that can be provided with traditional overlay VPNs. An enhanced VPN may be used for 5G transport network slicing, and will also be of use in more generic scenarios. This document specifies the IGP mechanisms with necessary extensions to build a set of Segment Routing (SR) based virtual networks with customized topology and resource attributes in the network. These virtual networks could be used as the underlay of enhanced VPN service. The proposed mechanism is applicable to both Segment Routing with MPLS data plane (SR-MPLS) and segment routing with IPv6 data plane (SRv6).

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 7, 2020.

## [1.](#) Introduction

Driven largely by needs arising from the 5G mobile network, the concept of network slicing has gained traction. There is a need to provide VPN service with enhanced isolation and performance characteristics. Specifically, there is a need for a transport network to provide a set of virtual networks, each of which provides the tenant with a customized network topology, the required degree of isolation and performance guarantee to meet the tenant's requirement.

These properties cannot be met with pure overlay networks, as they require integration between the underlay and the overlay networks. [[I-D.ietf-teas-enhanced-vpn](#)] specifies the framework of enhanced VPN and describes the candidate component technologies in different network planes and layers.

To meet the requirement of enhance VPN services, a number of virtual networks need be created, each with a subset of the underlay network topology and a set of network resources allocated to meet the requirement of a specific enhanced VPN or a group of enhanced VPNs. In the context of 5G, each virtual network can be considered as a transport network slice. Depending on the service requirement and the physical network infrastructure, different virtual networks may share the same network links or nodes, or use separate links or nodes, in both cases the level of isolation and service performance required by the tenant should be met.

[I-D.dong-spring-sr-for-enhanced-vpn] specifies how segment routing (SR) [[RFC8402](#)] can be used to build virtual networks with the required network topology and network resources to support enhanced VPN services. With segment routing based data plane, Segment Identifiers (SIDs) can be used to represent the topology and the set of network resources allocated by network nodes to a virtual network. The SIDs and the associated topology and resource information need to be distributed using a control plane.

[I-D.dong-teas-enhanced-vpn-control-plane] describes the requirements and considerations about the control plane of enhanced VPN. In order to support the increasing number of transport network slices in one network, the proposed approach is to separate the topology and resource attributes of the virtual network in control plane, so that the advertisement and processing of each type of attribute could be decoupled.

This document specifies the IGP control plane mechanism with necessary extensions to build a set of SR based transport network slices with customized topology and resource attributes. The proposed mechanism is applicable to both segment routing with MPLS data plane (SR-MPLS) and segment routing with IPv6 data plane (SRv6).

In general this approach applies to both IS-IS and OSPF, while the specific protocol extensions and encodings are different. In the current version of this document, the required IS-IS extensions are described. The required OSPF extensions will be described in a future version or a separate document.

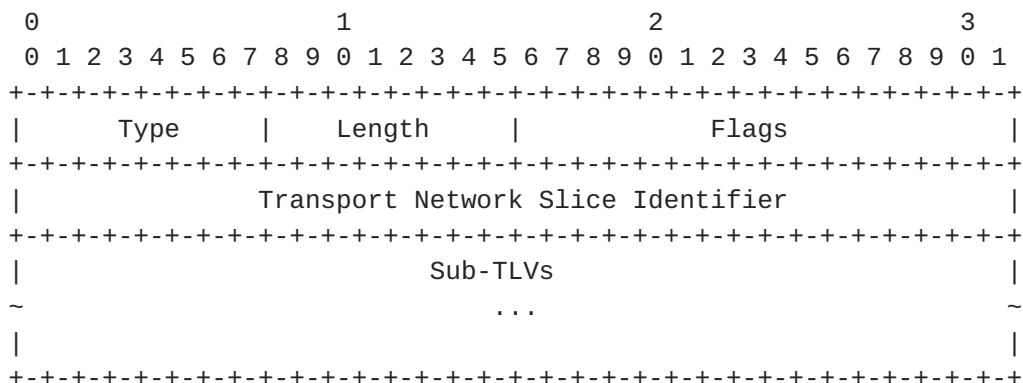

## **2. Transport Network Slice Definition Advertisement**

According to the definition in [[I-D.ietf-teas-enhanced-vpn](#)], a transport network slice is the combination of a set of network attributes, and the topology attribute and resource attributes are two major types of attributes of a transport network slice. In order to improve the control plane scalability, different types of attributes can be advertised and processed separately. IS-IS

Transport Network Slice Definition (TNSD) sub-TLV is used to advertise the definition of a transport network slice. It is a sub-TLV of the IS-IS Router-Capability TLV 242 as defined in [[RFC7981](#)].

The format of IS-IS TNSD sub-TLV is as below:

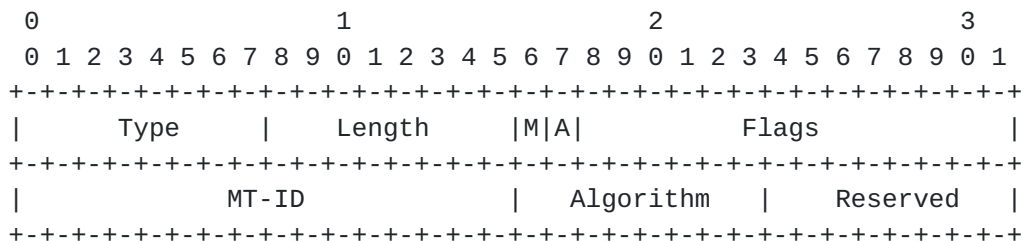

Where:

- o Type: TBD
- o Length: the length of the value field of the sub-TLV. It is variable dependent on the included sub-TLVs.
- o Flags: 16-bit flags to indicate the attributes of the virtual network. All flags are reserved and MUST be set to zero on transmission and ignored on receipt.
- o Transport Network Slice Identifier (TNSI): A 32-bit identifier which is used to identify a transport network slice.
- o Sub-TLVs: optional sub-TLVs to specify the attributes of a transport network slice.

Two sub-TLVs are defined in this document: Network Topology sub-TLV and Network Resource sub-TLV.

The format of the Network Topology sub-TLV is as below:

Resource Identifier: A 32-bit identifier which is used to identify the group of network resources allocated to a transport network slice.

### **3. Advertisement of Network Topology Attribute**

Two candidate mechanisms can be used to describe and advertise the topology attributes of SR based transport network slice. The first approach is to use Multi-Topology Routing (MTR) [[RFC4915](#)] [[RFC5120](#)] together with segment routing extensions to advertise the topologies of SR based transport network slices. The second approach is to use Flex- Algo [[I-D.ietf-lsr-flex-algo](#)] to describe the topological constraints of SR based transport network slice.

#### **3.1. MTR based Topology Advertisement**

Multi-Topology Routing (MTR) has been defined in [[RFC4915](#)] and [[RFC5120](#)] to create different network topologies in one network. It also has the capability of specifying customized attributes for each topology. The traditional use cases of multi-topology are to maintain separate topologies for unicast and multicast services, or to create different topologies for IPv4 and IPv6 in a network. There are some limitations when MTR is used with IP forwarding, the considerations about MT based IP forwarding are described in [[RFC5120](#)].

MTR can be used with SR-MPLS data plane.

[[I-D.ietf-isis-segment-routing-extensions](#)] specifies the IS-IS extensions to support SR-MPLS data plane, in which the Prefix-SID sub-TLVs can be carried in IS-IS TLV 235 (MT IP Reachability) and TLV 237 (MT IPv6 IP Reachability), and the Adj-SID sub-TLVs can be carried in IS-IS TLV 222 (MT-ISN) and TLV 223 (MT IS Neighbor Attribute).

MTR can also be used with SRv6 data plane.

[[I-D.ietf-lsr-isis-srv6-extensions](#)] specifies the IS-IS extensions to support SRv6 data plane, in which the MT-ID is included in the SRv6 Locator TLV. The SRv6 End SIDs inherit the topology/algorithm from the parent locator. In addition, the SRv6 End.X SID sub-TLVs can be carried in the IS-IS TLV 222 (MT-ISN) and TLV 223 (MT IS Neighbor Attribute).

These IGP extensions for SR-MPLS and SRv6 can be used to advertise and build the topology of SR based transport network slice.

#### **3.2. Flex-Algo based Topology Advertisement**

[[I-D.ietf-lsr-flex-algo](#)] specifies the mechanism to provide distributed computation of constrained paths, and how the SR-MPLS prefix-SIDs and SRv6 locators can be used to steer traffic along the constrained paths.

The Flex-Algo definition can be used to describe the topological constraints for path computation. According to the network nodes' participation of a Flex-Algo, and the rules of including or excluding specific Admin Groups (colors), a network topology can be determined by a Flex-Algo.

With the mechanism defined in [[I-D.ietf-lsr-flex-algo](#)], algorithm-specific prefix-SIDs can be allocated. This allows the nodes to steer traffic along distributed computed paths within the topology determined by the Flex-Algo.

[I-D.ietf-lsr-isis-srv6-extensions] specifies the IS-IS extensions to support SRv6 data plane, in which algorithm-specific SRv6 locators and SRv6 End SIDs can be allocated. This allows the nodes to steer traffic along distributed computed paths within the topology determined by the Flex-Algo. In addition, algorithm-specific SRv6 End.X SID can be allocated, which can be used to enforce traffic over the LFA computed backup path.

#### 4. Advertisement of Network Resource Attribute

This section specifies the mechanism to advertise the network resource attributes associated with a transport network slice. The mechanism of advertising link level resources is described. The mechanism and description of node resource are for further study.

On a physical network link, a subset of the link resource can be allocated to a specific transport network slice. This subset of the link resource can be represented as a virtual layer-2 member link of the physical link. In the L2 link bundle scenario, it is also possible that the subset of link resource is provided by a physical layer-2 member link.

[I-D.ietf-isis-l2bundles] describes the IS-IS extensions to advertise the link attributes of the L2 member links which comprise an L3 interface. Such mechanism can be extended to advertise the attributes of each physical or virtual member links, and the associated transport network slice.

A new flag "V" (Virtual) is defined in the flag field of the Parent L3 Neighbor Descriptor in the L2 Bundle Member Attributes TLV (25).

```

  0 1 2 3 4 5 6 7
+-+--+--+--+--+
|P|V|          |
+-+--+--+--+--+

```

The TE attributes of each physical or virtual bundle member link, such as the bandwidth and the adj-SIDs, can be advertised using the mechanism as defined in [\[I-D.ietf-isis-l2bundles\]](#).

## **5. Security Considerations**

This document introduces no additional security vulnerabilities to IS-IS and OSPF.

The mechanism proposed in this document is subject to the same vulnerabilities as any other protocol that relies on IGPs.

## **6. IANA Considerations**

IANA is requested to assign a new code point in the "sub-TLVs for TLV 242" registry.

Type: TBD

Description: Transport Network Slice Definition

IANA is requested to create a new sub-sub-TLV registry:

Registry: Sub-Sub-TLVs for Transport Network Slice Definition Sub-TLV

Registration Procedure: Expert review

Reference: This document

This document defines the following Sub-Sub-TLVs in the "Sub-Sub-TLVs for Transport Network Slice Definition Sub-TLV" registry:

Type: 1

Description: Network Topology Attribute

Reference: This document.

Type: 2

Description: Network Resource Attribute

Reference: This document

IANA is requested to assign a new code point in the "sub-TLVs for TLVs 22, 23, 25, 141, 222, and 223" registry.

Type: TBD

Description: Resource Identifier

## **7. Acknowledgments**

The authors would like to thank Mach Chen, Robin Li and Dean Cheng for their review and discussion of this document.
