**Updating TCP to support Rate-Limited Traffic  
draft-fairhurst-tcpm-newcwv-05**

Abstract

This document proposes an update to [RFC 5681](#) to address issues that arise when TCP is used to support traffic that exhibits periods where the sending rate is limited by the application rather than the congestion window. It updates TCP to allow a TCP sender to restart quickly following either an idle or rate-limited interval. This method is expected to benefit applications that send rate-limited traffic using TCP, while also providing an appropriate response if congestion is experienced.

It also evaluates TCP Congestion Window Validation, CWV, an IETF experimental specification defined in [RFC 2861](#), and concludes that CWV sought to address important issues, but failed to deliver a widely used solution. This document therefore proposes an update to the status of [RFC 2861](#) by recommending it is moved from Experimental to Historic status, and that it is replaced by the current specification.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 18, 2013.

## **1. Introduction**

TCP is used to support a range of application behaviours. The TCP congestion window (cwnd) controls the number of packets/bytes that a TCP flow may have in the network at any time. The unacknowledged volume of data that a TCP flow has in the network at a specific time is known as the FlightSize [[RFC5681](#)]. A bulk application will always have data available to transmit. The rate at which it sends is therefore limited by the maximum permitted by the receiver and congestion windows. In contrast, a rate-limited application will experience periods when the sender is either idle or is unable to send at the maximum rate permitted by the cwnd. This latter case is called rate-limited. The focus of this document is on the operation of TCP in such an idle or rate-limited case.

Standard TCP [[RFC5681](#)] requires the cwnd to be reset to the restart window (RW) when an application becomes idle. [[RFC2861](#)] noted that this TCP behaviour was not always observed in current implementations. Recent experiments [[Bis08](#)] confirm this to still be the case.

Standard TCP does not impose additional restrictions on the growth of the cwnd when a TCP sender is rate-limited. A rate-limited sender may therefore grow a cwnd far beyond that corresponding to the current transmit rate, resulting in a value that does not reflect current information about the state of the network path the flow is using. Use of such an invalid cwnd may result in reduced application performance and/or could significantly contribute to network congestion.

[[RFC2861](#)] proposed a solution to these issues in an experimental method known as Congestion Window Validation (CWV). CWV was intended to help reduce cases where TCP accumulated an invalid cwnd. The use and drawbacks of using CWV with an application are discussed in [Section 2](#).

[Section 4](#) specifies an alternative to CWV that seeks to address the same issues, but does this in a way that is expected to mitigate the impact on an application that varies its sending rate. The method described applies to both a rate-limited and an idle condition.

## **2. Reviewing experience with TCP-CWV**

[RFC 2861](#) described a simple modification to the TCP congestion control algorithm that decayed the cwnd after the transition to a "sufficiently-long" idle period. This used the slow-start threshold (ssthresh) to save information about the previous value of the

congestion window. The approach relaxed the standard TCP behaviour [[RFC5681](#)] for an idle session, intended to improve application performance. CWV also modified the behaviour for a rate-limited session where a sender transmitted at a rate less than allowed by cwnd.

[RFC 2861](#) has been implemented in some mainstream operating systems as the default behaviour [[Bis08](#)]. Analysis (e.g. [[Bis10](#)]) has shown that a TCP sender using CWV is able to use available capacity on a shared path after an idle period. This can benefit some applications, especially over long delay paths, when compared to the slow-start restart specified by standard TCP. However, CWV would only benefit an application if the idle period were less than several Retransmission Time Out (RTO) intervals [[RFC6298](#)], since the behaviour would otherwise be the same as for standard TCP, which resets the cwnd to the RTCP Restart Window (RW) after this period.

Experience with CWV suggests that although CWV benefits the network in a rate-limited scenario (reducing the probability of network congestion), the behaviour can be too conservative for many common rate-limited applications. This mechanism does not therefore offer the desirable increase in application performance for rate-limited applications and it is unclear whether applications actually use this mechanism in the general Internet.

It is therefore concluded that CWV is often a poor solution for many rate-limited applications. It has the correct motivation, but has the wrong approach to solving this problem.

### **3. Terminology**

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

The document assumes familiarity with the terminology of TCP congestion control [[RFC5681](#)].

The following new terminology is introduced:

Validated phase: The phase where the cwnd reflects a current estimate of the available path capacity.

Non-validated phase: The phase where the cwnd reflects a previous measurement of the available path capacity.

Non-validated period, NVP: The maximum period for which cwnd is

preserved in the non-validated phase.

Rate-limited: A TCP flow that does not consume more than one half of cwnd, and hence operates in the non-validated phase.

pipe ACK: The measured volume of data that was acknowledged by the network per RTT.

#### **4. An updated TCP response to idle and application-limited periods**

This section proposes an update to the TCP congestion control behaviour during an idle or rate-limited period. The new method permits a TCP sender to preserve the cwnd when an application becomes idle for a period of time (to be known as the non-validated period, NVP, see [section 5](#)). This period, where actual usage is less than allowed by cwnd, is named as the non-validated phase. This method allows an application to resume transmission at a previous rate without incurring the delay of slow-start. However, if the TCP sender experiences congestion using the preserved cwnd, it is required to immediately reset the cwnd to an appropriate value specified by the method. If a sender does not take advantage of the preserved cwnd within the NVP, the value of cwnd is reduced, ensuring the value better reflects the capacity that was recently actually used.

The method requires that the TCP SACK option is enabled. This allows the sender to select a cwnd following a congestion event that is based on the measured path capacity, better reflecting the fair-share. A similar approach was proposed by TCP Jump Start [[Liu07](#)], as a congestion response after more rapid opening of a TCP connection.

It is expected that this update will satisfy the requirements of many rate-limited applications and at the same time provide an appropriate method for use in the Internet. It also reduces the incentive for an application to send data simply to keep transport congestion state. (This is sometimes known as "padding").

The new method does not differentiate between times when the sender has become idle or rate-limited. This is partly a response to recognition that some applications wish to transmit at a rate less than allowed by the sender cwnd, and that it can be hard to make a distinction between rate-limited and idle behaviour. This is expected to encourage applications and TCP stacks to use standards-based congestion control methods. It may also encourage the use of long-lived connections where this offers benefit (such as persistent http).

The method is specified in following subsections.

#### **4.1. A method for preserving cwnd during the idle and application-limited periods.**

The method described in this document updates [[RFC5681](#)]. Use of the method REQUIRES a TCP sender and the corresponding receiver to enable the TCP SACK option [[RFC3517](#)].

[RFC5681] defines a variable FlightSize that indicates the amount of outstanding data in the network. This is assumed to be equal to the value of Pipe calculated based on the pipe algorithm [[RFC3517](#)]. In [RFC5681](#) this value is used during loss recovery, whereas in this method a new variable "pipeACK" is introduced and used to determine if the sender has validated the cwnd.

A sender is not required to continuously track the pipeACK value, but MUST set this variable to the volume of data that was acknowledged by the network per measured Round Trip Time (RTT), with a sampling period of not less than one measurement for  $\text{Min}(\text{RTT}, 1 \text{ second})$ . Using the variables defined in [[RFC3517](#)]. This could be implemented by caching the value of HighACK and after one RTT assigning pipeACK to the difference between the cached HighACK value and the current HighACK value. Other equivalent methods may be used.

#### **4.2. The nonvalidated phase**

The updated method creates a new TCP sender phase that captures whether the cwnd reflects a validated or non-validated value. The phases are defined as:

- o Validated phase:  $\text{pipeACK} \geq (1/2) * \text{cwnd}$ . This is the normal phase, where cwnd is expected to be an approximate indication of the available capacity currently available along the network path, and the standard methods are used to increase cwnd (currently [[RFC5681](#)]). The rule for transitioning to the non-validated phase is specified in [section 4.3](#).
- o Non-validated phase:  $\text{pipeACK} < (1/2) * \text{cwnd}$ . This is the phase where the cwnd has a value based on a previous measurement of the available capacity, and the usage of this capacity has not been validated in the previous RTT. That is, when it is not known whether the cwnd reflects the currently available capacity along the network path. The mechanisms to be used in this phase seek to determine a safe value for cwnd and an appropriate reaction to congestion. These mechanisms are specified in [section 4.3](#).

A sender starts a TCP connection in the Validated phase.

The values  $1/2$  was selected to reduce the effects of variations in the measured pipeACK, and to allow the sender some flexibility in when it sends data.

### **4.3. TCP congestion control during the nonvalidated phase**

A TCP sender MUST enter the non-validated phase when the measured pipeACK is less than  $(1/2)*cwnd$ .

A TCP sender that enters the non-validated phase will preserve the cwnd (i.e., this neither grows nor reduces while the sender remains in this phase). The phase is concluded after a fixed period of time (the NVP, as explained in [section 4.3.2](#)) or when the sender transmits sufficient data so that  $pipeACK > (1/2)*cwnd$  (i.e. it is no longer rate-limited).

The behaviour in the non-validated phase is specified as:

- o The cwnd is not increased when ACK packets are received in this phase.
- o If the sender receives an indication of congestion while in the non-validated phase (i.e. detects loss, or an Explicit Congestion Notification, ECN, mark [[RFC3168](#)]), the sender MUST exit the non-validated phase (reducing the cwnd as defined in [section 4.3.1](#)).
- o If the Retransmission Time Out (RTO) expires while in the non-validated phase, the sender MUST exit the non-validated phase. It then resumes using the Standard TCP RTO mechanism [[RFC5681](#)]. (The resulting reduction of cwnd described in [section 4.3.2](#) is appropriate, since any accumulated path history is considered unreliable).
- o A sender that measures a pipeACK greater than  $(1/2)*cwnd$  SHOULD enter the validated phase. (A rate-limited sender will not normally be impacted by whether this is in a validated or non-validated phase, since it will normally not consume the entire cwnd. However a change to the validated phase will release the sender from constraints on the growth of cwnd, and restore the use of the standard congestion response.)

#### **4.3.1. Response to congestion in the nonvalidated phase**

Reception of congestion feedback while in the non-validated phase is interpreted as an indication that it was inappropriate for the sender to use the preserved cwnd. The sender is therefore required to quickly reduce the rate to avoid further congestion. Since the cwnd does not have a validated value, a new cwnd value must be selected

based on the utilised rate.

A sender that detects a packet-drop or receives an ECN marked packet MUST calculate a safe cwnd, by setting it to the value specified in [Section 3.2 of \[RFC5681\]](#).

At the end of the recovery phase, the TCP sender MUST reset the cwnd using the method below:

$$\text{cwnd} = ((\text{FlightSize} - R)/2).$$

Where, R is the volume of data that was reported as unacknowledged by the SACK information. This follows the method proposed for Jump Start [[Liu07](#)].

The inclusion of the term R makes this adjustment more conservative than standard TCP. (This is required, since the sender may have sent more segments than a Standard TCP sender would have done. The additional reduction is beneficial when the FlightSize significantly overshoots the available path capacity incurring significant loss, for instance an intense traffic burst following a non-validated period.)

If the sender implements a method that allows it to identify the number of ECN-marked segments within a window that were observed by the receiver, the sender SHOULD use the method above, further reducing R by the number of marked segments.

#### **[4.3.2.](#) Adjustment at the end of the nonvalidated phase**

During the non-validated phase, a sender can produce bursts of data of up to the cwnd in size. While this is no different to standard TCP, it is desirable to control the maximum burst size, e.g. by setting a burst size limit, using a pacing algorithm, or some other method [[Hug01](#)].

An application that remains in the non-validated phase for a period greater than the NVP is required to adjust its congestion control state. If the sender exits the non-validated phase after this period, it MUST update the ssthresh:

$$\text{ssthresh} = \max(\text{ssthresh}, 3*\text{cwnd}/4).$$

(This adjustment of ssthresh ensures that the sender records that it has safely sustained the present rate. The change is beneficial to rate-limited flows that encounter occasional congestion, and could otherwise suffer an unwanted additional delay in recovering the sending rate.)

The sender MUST then update cwnd to be not greater than:

$$\text{cwnd} = \max(1/2 * \text{cwnd}, \text{IW}).$$

Where IW is the TCP initial window [[RFC5681](#)].

(This adjustment ensures that sender responds conservatively at the end of the non-validated phase by reducing the cwnd to better reflect the current sending rate of the sender. The cwnd update does not take into account FlightSize or pipeACK as these values only reflects the last RTT worth of data and do not reflect the average of peak sending rate.)

After completing this adjustment, the sender MAY re-enter the non-validated phase, if required (see [section 4.2](#)).

## 5. Determining a safe period to preserve cwnd

This section documents the rationale for selecting the maximum period that cwnd may be preserved, known as the non-validated period, NVP.

Preserving cwnd avoids undesirable side effects that would result if the cwnd were to be preserved for an arbitrary long period, which was a part of the problem that CWV originally attempted to address. The period a sender may safely preserve the cwnd, is a function of the period that a network path is expected to sustain the capacity reflected by cwnd. There is no ideal choice for this time.

A period of five minutes was chosen for this NVP. This is as a compromise that was larger than the idle intervals of common applications, but not sufficiently larger than the period for which the capacity of an Internet path may commonly be regarded as stable. The capacity of wired networks is usually relatively stable for periods of several minutes and that load stability increases with the capacity. This suggests that cwnd may be preserved for at least a few minutes.

There are cases where the TCP throughput exhibits significant variability over a time less than five minutes. Examples could include wireless topologies, where TCP rate variations may fluctuate on the order of a few seconds as a consequence of medium access protocol instabilities. Mobility changes may also impact TCP performance over short time scales. Senders that observe such rapid changes in the path characteristic may also experience increased congestion with the new method, however such variation would likely also impact TCP's behaviour when supporting interactive and bulk

applications.

Routing algorithms may modify the network path, disrupting the RTT measurement and changing the capacity available to a TCP connection, however such changes do not often occur within a time frame of a few minutes.

The value of five minutes is therefore expected to be sufficient for most current applications. Simulation studies also suggest that for many practical applications, the performance using this value will not be significantly different to that observed using a non-standard method that does not reset the cwnd after idle.

Finally, other TCP sender mechanisms have used a 5 minute timer, and there could be simplifications in some implementations by reusing the same interval. TCP defines a default user timeout of 5 minutes [[RFC0793](#)] i.e. how long transmitted data may remain unacknowledged before a connection is forcefully closed.

## **6. Security Considerations**

General security considerations concerning TCP congestion control are discussed in [[RFC5681](#)]. This document describes an algorithm that updates one aspect of the congestion control procedures, and so the considerations described in [RFC 5681](#) also apply to this algorithm.

## **7. IANA Considerations**

There are no IANA considerations.

## **8. Acknowledgments**

The authors acknowledge the contributions of Dr I Biswas and Dr R Secchi in supporting the evaluation of CWV and for their help in developing the mechanisms proposed in this draft. We also acknowledge comments received from the Internet Congestion Control Research Group, in particular Yuchung Cheng, Mirja Kuehlewind, and Joe Touch.

## **9. Author Notes**

### [9.1.](#) Other related work

There are several issues to be discussed more widely:

- o Should the method explicitly state a procedure for limiting burstiness or pacing?

This is often regarded as good practice, but is not presently a formal part of TCP. [draft-hughes-restart-00.txt](#) provides some discussion of this topic.

- o There are potential interaction with the proposal to raise the TCP initial Window to ten segments, do these cases need to be elaborated?

This relates to [draft-ietf-tcpm-initcwnd](#).

The two methods have different functions and different response to loss/congestion.

IW=10 proposes an experimental update to TCP that would allow faster opening of the cwnd, and also a large (same size) restart window. This approach is based on the assumption that many forward paths can sustain bursts of up to ten segments without (appreciable) loss. Such a significant increase in cwnd must be matched with an equally large reduction of cwnd if loss/congestion is detected, and such a congestion indication is likely to require future use of IW=10 to be disabled for this path for some time. This guards against the unwanted behaviour of a series of short flows continuously flooding a network path without network congestion feedback.

In contrast, new-CWV proposes a standards-track update with a rationale that relies on recent previous path history to select an appropriate cwnd after restart.

The behaviour differs in three ways:

- 1) For applications that send little initially, new-cwv may constrain more than IW=10, but would not require the connection to reset any path information when a restart incurred loss. In contrast, new-cwv would allow the TCP connection to preserve the cached cwnd, any loss, would impact cwnd, but not impact other flows.

2) For applications that utilise more capacity than provided by a `cwnd=10`, this method would permit a larger restart window compared to a restart using `IW=10`. This is justified by the recent path history.

3) new-CWV is intended to also be used for rate-limited applications, where the application sends, but does not seek to fully utilise the `cwnd`. In this case, new-cwv constrains the `cwnd` to that justified by the recent path history. The performance trade-offs are hence different, and it would be possible to enable new-cwv when also using `IW=10`, and yield the benefits of this.

- o There is potential overlap with the Laminar proposal ([draft-mathis-tcpm-tcp-laminar](#))

The current draft was intended as a standards-track update to TCP, rather than a new transport variant. At least, it would be good to understand how the two interact and whether there is a possibility of a single method.

## **9.2. Revision notes**

Draft 03 was submitted to ICCRG to receive comments and feedback.

Draft 04 contained the first set of clarifications after feedback:

- o Changed name to application limited and used the term rate-limited in all places.
- o Added justification and many minor changes suggested on the list.
- o Added text to tie-in with more accurate ECN marking.
- o Added ref to Hug01

Draft 05 contained various updates:

- o New text to redefine how to measure the acknowledged pipe, differentiating this from the `FlightSize`, and hence avoiding previous issues with infrequent large bursts of data not being validated. A key point new feature is that `pipeACK` only triggers leaving the NVP after the size of the pipe has been acknowledged. This removed the need for hysteresis.

- o Reduction values were changed to 1/2, following analysis of suggestions from ICCRG. This also sets the "target" cwnd as twice the used rate for non-validated case.
- o Introduced a symbolic name (NVP) to denote the 5 minute period.
