**ACME Integrations**  
**draft-friel-acme-integrations-00**

Abstract

This document outlines multiple advanced use cases and integrations that ACME facilitates without any modifications or enhancements required to the base ACME specification. These use cases are not immediately obvious from reading the ACME specification and thus are explicitly documented here. The use cases include ACME issuance of subdomain certificates, and ACME integration with EST and TEAP.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 14, 2019.

## [1.](#) Introduction

ACME [[RFC8555](#)] defines a protocol that a certificate authority (CA) and an applicant can use to automate the process of domain name ownership validation and X.509 (PKIX) certificate issuance. The protocol is rich and flexible and enables multiple use cases that are not immediately obvious from reading the specification. This document explicitly outlines multiple advanced ACME use cases including:

- o ACME issuance of subdomain certificates
- o ACME integration with EST [[RFC7030](#)]
- o ACME integration with BRSKI  
[[I-D.ietf-anima-bootstrapping-keyinfra](#)]
- o ACME integration with TEAP [[RFC7170](#)]
- o ACME integration with TEAP-BRSKI [draft-lear-eap-teap-brski](#)

## [2.](#) Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#) [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

The following terms are used in this document:

- o BRSKI: Bootstrapping Remote Secure Key Infrastructures [[I-D.ietf-anima-bootstrapping-keyinfra](#)]
- o CA: Certificate Authority
- o CMC: Certificate Management over CMS
- o CSR: Certificate Signing Request
- o EST: Enrollment over Secure Transport [[RFC7030](#)]
- o FQDN: Fully Qualified Domain Name
- o RA: PKI Registration Authority
- o TEAP: Tunnelled Extensible Authentication Protocol [[RFC7170](#)]

### **3. ACME Issuance of Subdomain Certificates**

A typical ACME workflow for issuance of certificates is as follows:

1. client POSTs a newOrder request that contains a set of "identifiers"
2. server replies with a set of "authorizations" and a "finalize" URI
3. client sends POST-as-GET requests to retrieve the "authorizations", with the downloaded "authorization" object(s) containing the "identifier" that the client must prove control of
4. client proves control over the "identifier" in the "authorization" object by completing the specified challenge, for example, by publishing a DNS TXT record
5. client POSTs a CSR to the "finalize" API

ACME places the following restrictions on "identifiers":

- o [section 7.1.4](#): the only type of "identifier" defined by the ACME specification is a fully qualified domain name

The only type of identifier defined by this specification is a fully qualified domain name (type: "dns"). The domain name MUST be encoded in the form in which it would appear in a certificate.

- o [Section 7.4](#): the "identifier" in the CSR request must match the "identifier" in the newOrder request

The CSR MUST indicate the exact same set of requested identifiers as the

initial newOrder request.

Expires November 14, 2019

[Page 3]

- o Sections [8.3](#) and [8.4](#): the "identifier", or FQDN, in the "authorization" object must be used when fulfilling challenges via HTTP or DNS mechanisms

Construct a URL by populating the URL template [[RFC6570](#)]  
 "http://{domain}/.well-known/acme-challenge/{token}", where:

- \* the domain field is set to the domain name being verified

The client constructs the validation domain name by prepending the label "\_acme-challenge" to the domain name being validated

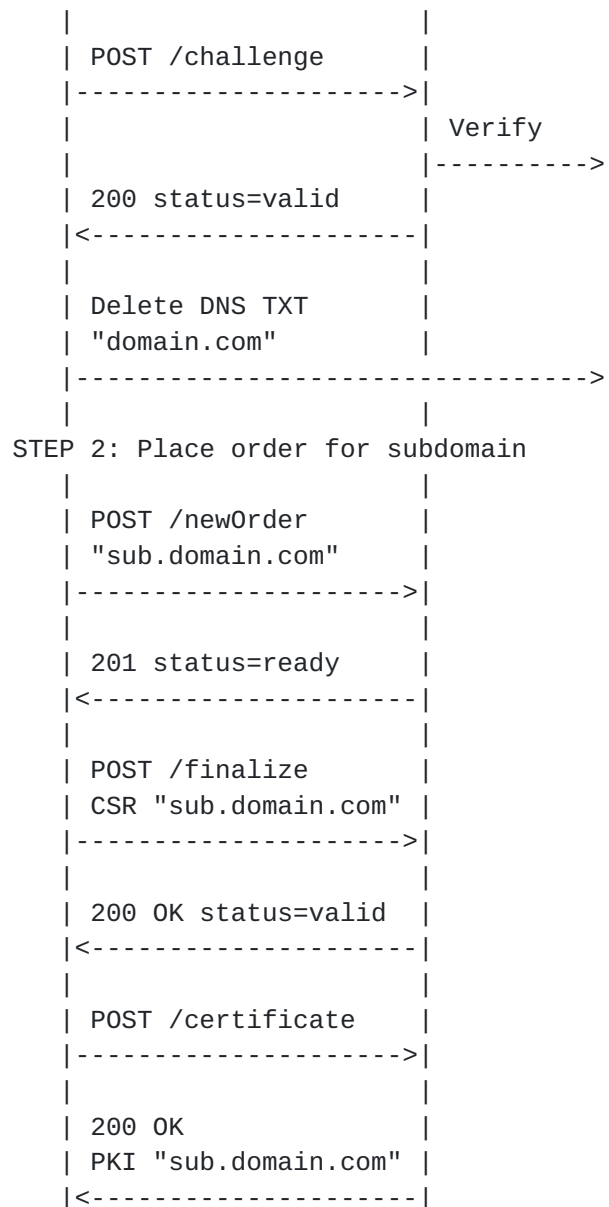

ACME does not mandate that the "identifier" in a newOrder request matches the "identifier" in "authorization" objects. This means that the ACME specification does not preclude an ACME server processing newOrder requests and issuing certificates for a subdomain without requiring a challenge to be fulfilled against that explicit subdomain. ACME server policy could allow issuance of certificates for a subdomain to a client where the client only has to fulfill an authorization challenge for the parent domain.

This allows a flow where a client proves ownership of "domain.com" and then successfully obtains a certificate for "sub.domain.com". The ACME pre-authorization flow makes most sense for this use case, and that is what is illustrated in the following call flow.

The client could pre-authorize for the parent domain once, and then issue multiple newOrder requests for certificates for multiple subdomains. This call flow illustrates the client only placing one newOrder request.

+-----+	+-----+	+-----+
Client	ACME	DNS
+-----+	+-----+	+-----+
STEP 1: Pre-Authorization of parent domain		
POST /newAuthz		
"domain.com"		
----->		
201 authorizations		
<-----		
Publish DNS TXT		
"domain.com"		
----->		

#### 4. ACME Integration with EST

EST [[RFC7030](#)] defines a mechanism for clients to enroll with a PKI Registration Authority by sending CMC messages over HTTP. EST [section 1](#) states:

Architecturally, the EST service is located between a Certification Authority (CA) and a client. It performs several functions traditionally allocated to the Registration Authority (RA) role in a PKI.

EST [section 1.1](#) states that:

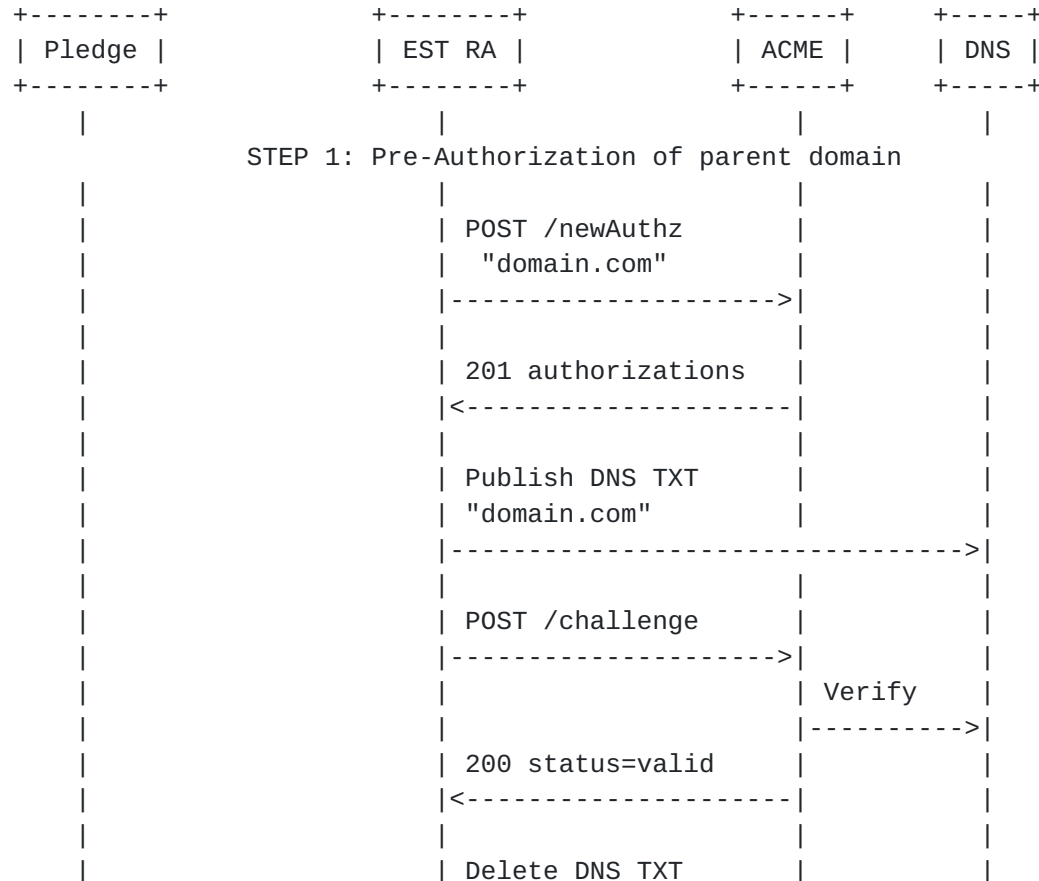

For certificate issuing services, the EST CA is reached through the EST server; the CA could be logically "behind" the EST server or embedded within it.

When the CA is logically "behind" the EST RA, EST does not specify how the RA communicates with the CA. EST [section 1](#) states:

The nature of communication between an EST server and a CA is not described in this document.

This section outlines how ACME could be used for communication between the EST RA and the CA. The example call flow shows the RA proving ownership of a parent domain, with individual client certificates being subdomains under that parent domain. This is an optimisation that reduces DNS and ACME traffic overhead. The RA could of course prove ownership of every explicit client certificate identifier.

The call flow also illustrates how the RA can include relevant domain information in the CSR request to ACME that the client may not have knowledge of. For example, a device or pledge may know its MAC address and serial number and only include that as its identifier in a CSR request. The RA could insert the domain information into the CSR request. Additionally, for privacy reasons, the RA may not want to divulge MAC or serial number information to the CA and could additionally assign an opaque random identifier to the device.

| PKI "pledgeX.domain.com"
|<-----
|
| STEP 4: Pledge retries enroll
|
| POST /simpleenroll
| PCSK#10 "MAC/serial"
|----->
|
| 200 OK
| PKCS#7 "pledgeX.domain.com"
|<-----

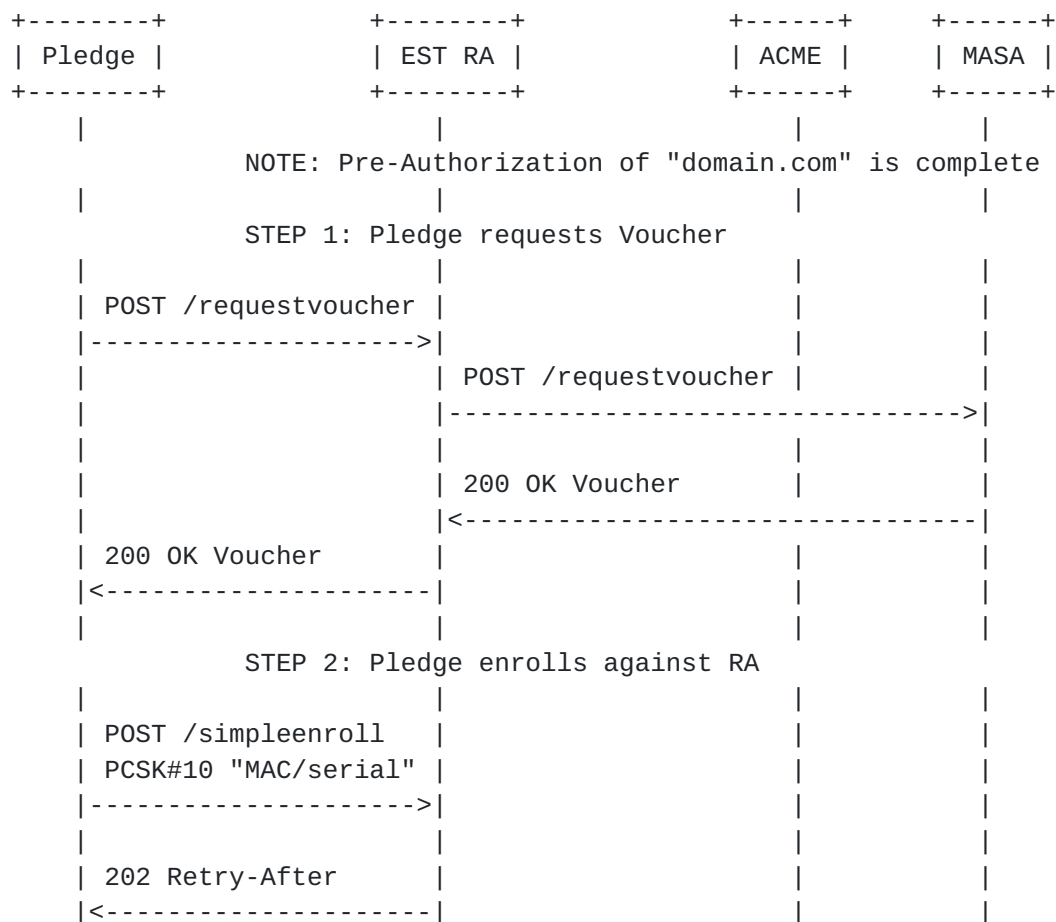

```

## 5. ACME Integration with BRSKI

BRSKI [[I-D.ietf-anima-bootstrapping-keyinfra](#)] is based upon EST [[RFC7030](#)] and defines how to autonomically bootstrap PKI trust anchors into devices via means of signed vouchers. EST certificate enrollment may then optionally take place after trust has been established. BRSKI voucher exchange and trust establishment are based on EST extensions and the certificate enrollment part of BRSKI is fully based on EST. Similar to EST, BRSKI does not define how the EST RA communicates with the CA. Therefore the mechanisms outlined in the previous section for using ACME as the communications protocol between the EST RA and the CA are equally applicable to BRSKI.

The following call flow shows how ACME may be integrated into a full BRSKI voucher plus EST enrollment workflow. For brevity, it assumes that the EST RA has previously proven ownership of a parent domain and that pledge certificate identifiers are a subdomain of that parent domain. The domain ownership exchanges between the RA, ACME and DNS are not shown. Similarly, not all BRSKI interactions are shown and only the key protocol flows involving voucher exchange and EST enrollment are shown.

```

|                                     |
| STEP 3: RA places ACME order      |
|                                     |
| POST /newOrder                    |
| "pledgeX.domain.com"             |
| ----->                          |
| 201 status=ready                  |
| <-----                          |
| POST /finalize                    |
| CSR "pledgeX.domain.com"         |
| ----->                          |
| 200 OK status=valid              |
| <-----                          |
| POST /certificate                  |
| ----->                          |
| 200 OK                            |
| PKI "pledgeX.domain.com"         |
| <-----                          |
|
| STEP 4: Pledge retries enroll    |
|
| POST /simpleenroll                |
| PCSK#10 "MAC/serial"             |
| ----->                          |
| 200 OK                            |
| PKCS#7 "pledgeX.domain.com"      |
| <-----                          |

```

## 6. ACME Integration with TEAP

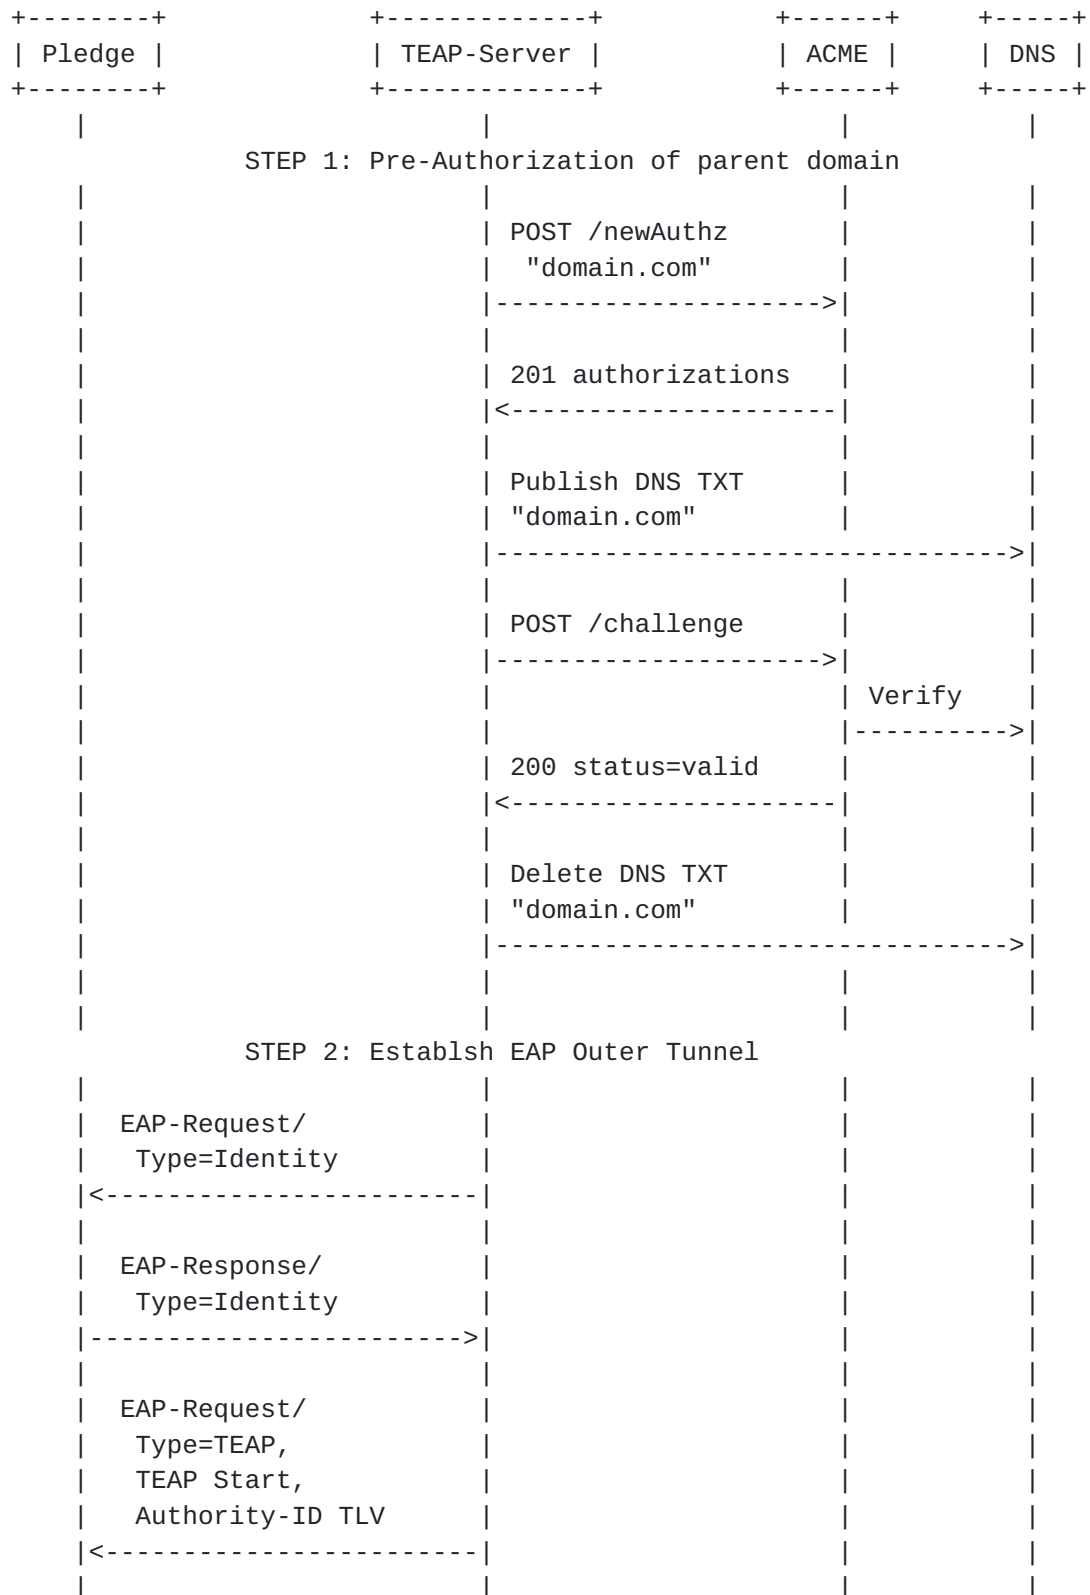

TEAP [RFC7170] define a tunnel-based EAP method that enables secure communication between a peer and a server by using TLS to establish a mutually authenticated tunnel. TEAP enables certificate provisioning within the tunnel. TEAP does not define how the TEAP server communicates with the CA.

This section outlines how ACME could be used for communication between the TEAP server and the CA. The example call flow shows the TEAP server proving ownership of a parent domain, with individual client certificates being subdomains under that parent domain. This is an optimisation that reduces DNS and ACME traffic overhead. The

TEAP server could of course prove ownership of every explicit client certificate identifier.

```

| EAP-Response/
|   Type=TEAP,
|   TLS(ClientHello)
| ----->
|
| EAP-Request/
|   Type=TEAP,
|   TLS(ServerHello,
|     Certificate,
|     ServerKeyExchange,
|     CertificateRequest,
|     ServerHelloDone)
| <-----
|
| EAP-Response/
|   Type=TEAP,
|   TLS(Certificate,
|     ClientKeyExchange,
|     CertificateVerify,
|     ChangeCipherSpec,
|     Finished)
| ----->
|
| EAP-Request/
|   Type=TEAP,
|   TLS(ChangeCipherSpec,
|     Finished),
|   {Crypto-Binding TLV,
