Transport Layer Security Protocol Compression Using LZS
draft-friend-tls-lzs-compression-02.txt

Status of this Memo

This document is an Internet-Draft and is subject to all provisions of [Section 10 of RFC2026](#) except that the right to produce derivative works is not granted.

This memo provides information for the Internet community. It does not specify an Internet standard of any kind. Distribution of this memo is unlimited.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/1id-abstracts.html>

The list of Internet-Draft Shadow Directories can be accessed at
<http://www.ietf.org/shadow.html>

This Internet-Draft will expire on October 1, 2004.

It is intended that a future version of this draft be submitted to the IESG for publication as an Informational RFC. Copyright Notice

Abstract

The Transport Layer Security (TLS) protocol ([RFC 2246](#)) includes features to negotiate selection of a lossless data compression method as part of the TLS Handshake Protocol and to then apply the algorithm associated with the selected method as part of the TLS Record Protocol. TLS defines one standard compression method which specifies that data exchanged via the record protocol will not be compressed. [\[TLSComp\]](#) defines another compression method. This document describes an additional compression method associated with the LZS data compression algorithm for use with TLS. This document

1. Introduction

1.1 General

The Transport Layer Security (TLS) protocol ([RFC 2246](#), [2]) includes features to negotiate selection of a lossless data compression method as part of the TLS Handshake Protocol and to then apply the algorithm associated with the selected method as part of the TLS Record Protocol. TLS defines one standard compression method, `CompressionMethod.null`, which specifies that data exchanged via the record protocol will not be compressed. While this single compression method helps ensure that TLS implementations are interoperable, the lack of additional standard compression methods has limited the ability of implementers to develop interoperable implementations that include data compression.

TLS is used extensively to secure client-server connections on the World Wide Web. While these connections can often be characterized as short-lived and exchanging relatively small amounts of data, TLS is also being used in environments where connections can be long-lived and the amount of data exchanged can extend into thousands or millions of octets. For example, SSL is now increasingly being used as an alternative VPN connection. Compression services have long been associated with IPsec and PPTP VPN connections, so extending compression services to SSL VPN connections preserves the user experience for any VPN connection. Compression within TLS is one way to help reduce the bandwidth and latency requirements associated with exchanging large amounts of data while preserving the security services provided by TLS.

This document describes an additional compression method associated with a lossless data compression algorithm for use with TLS. This document specifies the application of LZS compression, a lossless compression algorithm, to TLS record payloads. This specification also assumes a thorough understanding of the TLS protocol [[TLS](#)].

1.2 Licensing

Software licenses for a reference implementation are available for use in IPPCP, IPsec, PPP, in addition to TLS applications at no cost.

Software licenses are available on a non-discriminatory basis. Hardware implementations are also available. For more information, contact Hifn at the address listed with the author's address.

1.3 Specification of Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC-2119](#)].

2. Compression Methods

As described in [section 6 of RFC 2246](#) [2], TLS is a stateful protocol. Compression methods used with TLS can be either stateful (the compressor maintains its state through all compressed records) or stateless (the compressor compresses each record independently), but there seems to be little known benefit in using a stateless compression method within TLS. The LZS compression method described in this document is stateful.

Compression algorithms can occasionally expand, rather than compress, input data. The worst case expansion factor of the LZS compression method is only 12.5%. Thus, TLS records of 15K bytes can never exceed the expansion limits described in [section 6.2.2 of RFC 2246](#) [2]. If TLS records of 16K bytes expand to greater than 17K bytes, then the uncompressed version of the TLS record must be transmitted, as described below.

2.1 LZS CompressionMethod

The LZS CompressionMethod is a 16-bit index, and is negotiated as described in [[TLS](#)] and [[TLSComp](#)]. The LZS CompressionMethod is stored in the TLS Record Layer connection state as described in [[TLS](#)].

IANA has assigned <TBD> as compression method identifier for applying LZS compression to TLS record payloads.

2.2 Security Issues with Compression Histories

Sharing compression histories between more than one TLS session may potentially cause information leakage between the TLS sessions, as pathological compressed data can potentially reference data prior to the beginning of the current record. LZS implementations guard against this situation. However, to avoid this potential threat from occurring, implementations that support TLS compression MUST use separate compression histories for each TLS session. This is not a limitation of LZS compression, but is an artifact for any compression algorithm.

Furthermore, the LZS compression history (as well as any compression history) contains plaintext. Specifically, the LZS history contains

the last 2K bytes of plaintext of the TLS session. Thus, when the TLS

Friend

Expires October 1, 2004

[Page 4]

session terminates, the implementation SHOULD treat the history as it does any plaintext (e.g. free memory, overwrite contents, etc.).

3. LZS Compression

3.1 Background of LZS Compression

Starting with a sliding window compression history, similar to [[LZ1](#)], Hifn developed a new, enhanced compression algorithm identified as LZS. The LZS algorithm is a general-purpose lossless compression algorithm for use with a wide variety of data types. It's encoding method is very efficient, providing compression for strings as short as two octets in length.

The LZS algorithm uses a sliding window of 2,048 bytes. During compression, redundant sequences of data are replaced with tokens that represent those sequences. During decompression, the original sequences are substituted for the tokens in such a way that the original data is exactly recovered. LZS differs from lossy compression algorithms, such as those often used for video compression, that do not exactly reproduce the original data. The details of LZS compression can be found in [[ANSI94](#)].

3.2 LZS Compression History and Packet Processing

This standard specifies "stateful" compression, that is, maintaining the compression history between records within a particular TLS compression session. Within each separate compression history, the LZS CompressionMethod has the ability to maintain compression history information when compressing and decompressing record payloads. Stateful compression provides a higher compression ratio to be achieved on the data stream as compared to stateless compression (resetting the compression history between every record), particularly for small records.

Stateful compression requires both a reliable link and sequenced packet delivery, to ensure all records can be decompressed in the same order they were compressed. Since TLS and lower-layer protocols provide reliable, sequenced packet delivery, compression history information MAY be maintained and exploited when using the LZS CompressionMethod.

Furthermore, there MUST be a separate LZS compression history associated with each open TLS session. This not only provides enhanced security (no potential information leakage between sessions via a shared compression history), but also enables superior compression ratio (bit bandwidth on the connection) across all open TLS sessions with compression. A shared history would require resetting the compression (and decompression) history when switching

between TLS sessions, and a single history implementation would require resetting the compression (and decompression) history

Friend

Expires October 1, 2004

[Page 5]

between each record.

The sender **MUST** reset the compression history prior to compressing the first TLS record of a TLS session after TLS handshake completes. It is advantageous for the sender to maintain the compression history for all subsequent records processed during the TLS session. This results in the greatest compression ratio for a given data set. In either case, this compression history **MUST NOT** be used for any other open TLS session, in order to ensure privacy between TLS sessions.

The sender **MUST** "flush" the compressor each time it transmits a compressed record. Flushing means that all data going into the compressor is included in the output, i.e., no data is retained in the hope of achieving better compression. Flushing ensures that each compressed packet payload can be decompressed completely. Flushing is necessary to prevent a record's data from spilling over into a later record. This is important to synchronize compressed data with the authenticated and encrypted data in a TLS record. Flushing is handled automatically in most LZS implementations.

When the TLS session terminates, the implementation **SHOULD** dispose of the memory resources associated with the related TLS compression history. That is, the compression history **SHOULD** be handled as the TLS key material is handled.

The LZS CompressionMethod also features "decompressing" uncompressed data in order to maintain the history in the case that the "compressed" data actually expanded. The LZS CompressionMethod record format facilitates identifying whether records contain compressed or uncompressed data. The LZS decoding process accommodates decompressing either compressed or uncompressed data.

3.3 LZS Compressed Record Format

Prior to compression, the uncompressed data (TLSPlaintext.fragment) comprises a plaintext TLS record. After compression, the compressed data (TLSCompressed.fragment) comprises a 8-bit TLSComp header followed by the compressed (or uncompressed) data.

3.4. TLSComp Header Format

The one-octet header has the following structure:

```

0
0 1 2 3 4 5 6 7
+--+--+--+--+--+--+
|      Flags      |
|                  |
+--+--+--+--+--+--+
```

Friend

Expires October 1, 2004

[Page 6]

3.4.1 Flags

The format of the 8-bit Flags TLSComp field is as follows:

0	1	2	3	4	5	6	7
Res	Res	Res	Res	Res	Res	RST	C/U

Res - Reserved

Reserved for future use. MUST be set to zero. MUST be ignored by the receiving node.

RST - Reset Compression History

The RST bit is used to inform the decompressing peer that the compression history in this TLS session was reset prior to the data contained in this TLS record being compressed. When the RST bit is set to "1" a compression history reset is performed, when RST is set to "0", a compression history reset is not performed.

This bit MUST be set to a value of "1" for the first compressed TLS transmitted record of a TLS session. This bit may also be used by the transmitter for other exception cases when the compression history must be reset.

C/U - Compressed/Uncompressed Bit

The C/U indicates whether the data field contains compressed or uncompressed data. A value of 1 indicates compressed data (often referred to as a compressed packet), and a value of 0 indicates uncompressed data (or an uncompressed packet).

3.5 LZS Compression Encoding Format

The LZS compression method, encoding format, and application examples are described in [RFC 1967](#) [7], [RFC 1974](#) [6], [RFC 2395](#) [5], and [\[ANSI94\]](#).

Some implementations of LZS allow the sending compressor to select from among several options to provide varying compression ratios, processing speeds, and memory requirements. Other implementations of LZS provide optimal compression ratio at byte per clock speeds.

The receiving LZS decompressor automatically adjusts to the settings selected by the sender. Also, receiving LZS decompressors will update the decompression history with uncompressed data. This facilitates

never obtaining less than 1:1 compression ratio (never transmit with

Friend

Expires October 1, 2004

[Page 7]

expanded data) in the session.

The input to the payload compression algorithm is TLSPlaintext data destined to an active TLS session with compression negotiated. The output of the algorithm is a new (and hopefully smaller) TLSCompressed record. The output payload contains the input payload's data in either compressed or uncompressed format. The input and output payloads are each an integral number of bytes in length.

The output payload is always prepended with the TLSComp header. If the uncompressed form is used, the output payload is identical to the input payload, and the TLSComp header reflects uncompressed data.

If the compressed form is used, encoded as defined in [\[ANSI94\]](#), and the TLSComp header reflects compressed data. The LZS encoded format is repeated here for informational purposes ONLY.

<Compressed Stream> := [<Compressed String>*] <End Marker>

<Compressed String> := 0 <Raw Byte> | 1 <Compressed Bytes>

<Raw Byte> := (8-bit byte)

<Compressed Bytes> := <Offset> <Length>

<Offset> := 1 | (7-bit offset)
0 (11-bit offset)

<End Marker> := 110000000

 := 1 | 0

<Length> :=

00	= 2	1111 0110	= 14
01	= 3	1111 0111	= 15
10	= 4	1111 1000	= 16
1100	= 5	1111 1001	= 17
1101	= 6	1111 1010	= 18
1110	= 7	1111 1011	= 19
1111 0000	= 8	1111 1100	= 20
1111 0001	= 9	1111 1101	= 21
1111 0010	= 10	1111 1110	= 22
1111 0011	= 11	1111 1111 0000	= 23
1111 0100	= 12	1111 1111 0001	= 24
1111 0101	= 13	...	

[3.6](#) Padding

A datagram payload compressed using LZS always ends with the last compressed data byte (also known as the <end marker>), which is used to disambiguate padding. This allows trailing bits as well as bytes to be considered padding.

The size of a compressed payload MUST be in whole octet units.

Friend

[Page 8]

4. Sending Compressed Datagrams

All TLS records processed with a TLS session state that includes LZS compression are processed as follows. The reliable and efficient transport of LZS compressed records in the TLS session depends on the following processes.

4.1. Transmitter Process

The compression operation results in either compressed or uncompressed data. When a TLS record is received, it is assigned to a particular TLS context that includes the LZS compression history buffer. It is processed according to ANSI X3.241-1994 to form compressed data or used as is to form uncompressed data. For the first record of the session, or for exception conditions, the compression history **MUST** be cleared. In performing the compression operation the compression history **MUST** be updated when either a compressed record or uncompressed record is produced. Uncompressed TLS records **MAY** be sent at any time. Uncompressed TLS records **MUST** be sent if compression causes enough expansion to cause the data compression TLS record size to exceed the MTU defined in [section 6.2.2 in RFC 2246](#).

The output of the compression operation is placed in the fragment field of the TLSCompressed structure (TLSCompressed.fragment).

The TLSComp header byte is located just prior to the first byte of the compressed TLS record in TLSCompressed.fragment. The C/U bit in the TLSComp header is set according to whether the data field contains compressed or uncompressed data. The RST bit in the TLSComp header is set to "1" if the compression history was reset prior to compressing the TLSplaintext.fragment that comprises TLSCompressed.fragment. Uncompressed data **MUST** be transmitted (and the C/U bit set to 0) if the "compressed" (expanded) data exceeded 17K bytes.

4.2. Receiver Process

Prior to decompressing the first compressed TLS record in the TLS session, the receiver **MUST** reset the decompression history. Subsequent records are decompressed in the order received. The receiver decompresses the Payload Data field according to the encoding specified in section 3.2 of [\[ANSI94\]](#).

If the received datagram is not compressed, the receiver needs to perform no decompression processing and the Payload Data field of the datagram is ready for processing by the next protocol layer.

After a TLS record is received from the peer and decrypted, the RST and C/U bits **MUST** be checked.

Friend

Expires October 1, 2004

[Page 9]

If the C/U bit is set to "1", the resulting compressed data block MUST be decompressed according to [[ANSI94](#)].

If the C/U bit is set to "0", the specified decompression history MUST be updated with the received uncompressed data.

If the RST bit is set to "1", the receiving decompression history MAY be reset to an initial state prior to decompressing the TLS record. (However, due to the characteristics of the Hifn LZS algorithm, a decompression history reset is not required). After reset, any compressed or uncompressed data contained in the packet is processed.

4.3. Anti-Expansion Mechanism

During compression, there are two options on how to handle packets that expand:

- 1) Send the expanded data (as long as TLSCompressed.length is 17K or less) and maintain the history, thus allowing loss of current bandwidth but preserving future bandwidth on the link.
- 2) Send the uncompressed data and do not clear the compression history; the decompressor will update its history, thus conserving the current bandwidth and future bandwidth on the link.

The second option is the preferred option, and SHOULD be implemented.

A third option:

- 3) Send the uncompressed data and clear the history, thus conserving current bandwidth, but allowing possible loss of future bandwidth on the link.

SHOULD NOT be implemented.

5. Internationalization Considerations

The compression method identifiers specified in this document are machine-readable numbers. As such, issues of human internationalization and localization are not introduced.

Friend

Expires October 1, 2004

[Page 11]

6. IANA Considerations

Section 2 of [[TLSComp](#)] describes a registry of compression method identifiers to be maintained by the IANA and to be assigned within three zones. IANA is requested to assign an identifier for the LZS compression method from the [RFC2434](#) Specification Required IANA pool as described in sections [2](#) and [5](#) of [[TLSComp](#)].

The IANA-assigned compression method identifier for LZS is TBD decimal (0xTBD).

[Page 12]

7. Security Considerations

This document does not introduce any topics that alter the threat model addressed by TLS. The security considerations described throughout [RFC 2246](#) [2] apply here as well.

However, combining compression with encryption can sometimes reveal information that would not have been revealed without compression: data that is the same length before compression might be a different length after compression, so adversaries that observe the length of the compressed data might be able to derive information about the corresponding uncompressed data. Some symmetric encryption ciphersuites do not hide the length of symmetrically encrypted data at all. Others hide it to some extent, but still don't hide it fully. For example, ciphersuites that use stream cipher encryption without padding do not hide length at all; ciphersuites that use Cipher Block Chaining (CBC) encryption with padding provide some length hiding, depending on how the amount of padding is chosen. Use of TLS compression SHOULD take into account that the length of compressed data may leak more information than the length of the original uncompressed data.

Another security issue to be aware of is that the LZS compression history contains plaintext. In order to prevent any kind of information leakage to outside the system, when a TLS session with compression terminates, the implementation SHOULD treat the compression history as it does plaintext, that is, care should be taken not to reveal the compression history in any form, or use it again. This is described both in sections [2.2](#) and [3.2](#) above.

This information leakage concept can be extended to the situation of sharing a single compression history across more than one TLS session, as addressed in [section 2.2](#) above.

Other security issues are discussed in [\[TLSComp\]](#).
