Thing-to-Thing Data Hub draft-hartke-t2trg-data-hub-02

Abstract

The Thing-to-Thing Data Hub is a RESTful, hypermedia-driven Web application that can be used in Thing-to-Thing communications to share data items such as thing descriptions, configurations, resource descriptions, or firmware updates at a central location.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of $\underline{\mathsf{BCP}}$ 78 and $\underline{\mathsf{BCP}}$ 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 25, 2019.

1. Introduction

In Thing-to-Thing communication, there is often a need to share data items of common interest at a central location. For example, the CORE Resource Directory [I-D.ietf-core-resource-directory] aggregates descriptions of resources held on other servers, which enables Things to easily discover these resources. Similarly, a W3C Web-of-Things Thing Description Repository [WOT] stores semantic metadata of Things as well as functional descriptions of their interfaces, making this data available to Web dashboards, commissioning tools and other things.

As more and more Thing-to-Thing applications are implemented, it becomes increasingly important to be able to share not only resource and Thing descriptions but also many other kinds of data, such as default configurations for new devices, service locations, firmware updates, or certificate revocation lists. The existing resource directories and Thing description repositories are not a good fit for these kinds of data, as they're specialized to their use cases and don't accept any other kinds of data. Creating a new, specialized application for each use case is not practical in the long term.

This document defines a simple "data hub" application, a RESTful Web application with a hypermedia API that is suitable for constrained environments and that generalizes the concept of a central repository to sharing any kinds of data. A data hub enables clients to share data items in any format and provides means for creating, reading, observing, updating, deleting, and finding data items at a data hub server.

Data hubs are intended to be used primarily with CoAP [RFC7252].

Features:

o General

The data hub generalizes the concept of a directory or repository to data items of any Internet media type. This means applications using the data hub aren't stuck forever with the same media types or limited to resource descriptions and Thing descriptions.

o Searchable

Clients can retrieve a subset of data items from a data hub based on item metadata.

o Observable

Data items published to a data hub are exposed as resources. As such, they can be observed for changes [RFC7641]. This allows clients to stay informed of information that other clients update over time. As a result, the data hub functions similar to a CoAP Publish-Subscribe Broker [I-D.ietf-core-coap-pubsub], although this isn't its primary use case.

o Evolvable

The key differentiator of the data hub compared to CoRE Resource Directory and CoAP Publish-Subscribe Broker is the evolvability -- the ability to respond effectively to the need for changes without negatively impacting existing and new clients. Data hubs enable fine-grained evolvability by driving all interactions by machine-readable hypermedia elements. Features can be added, changed or removed in a safe, backwards-compatible way simply by updating the data hub representation to expose appropriate links and forms.

1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

2. Data Model

The data model consists of three elements: the _data hub_, a _data collection_, and a number of shared _data items_ (Figure 1).

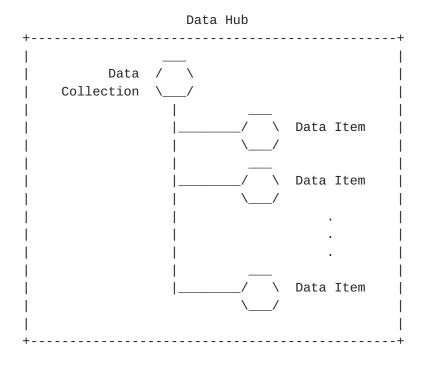

Figure 1: A Data Collection with a Number of Shared Data Items Hosted at a Data Hub

Data Hub

A data hub is a Web application running at a Web server. It hosts the data collection and the data items.

Data Collection

A data collection is a collection resource that contains the data items.

Representations of data collections MUST have the "application/coral+cbor" or "text/coral" media type [I-D.hartke-t2trg-coral]. They primarily consist of links to the data items using the "item" link relation type [RFC6573]. To reduce the number of round-trips, they MAY also embed (complete or partial) representations of the data items. Forms contained in the representation enable interactions with the collection and the data items, as described in the following section. The representations MAY additionally contain other links and forms that are not described in this document, such as a link with the "alternate" link relation type

that references an alternate representation of the data collection resource.

For a start, a data hub is defined to have a depth of only one level; i.e., all data item resources are organized directly under the top-level data collection resource. This could be extended to multiple levels in a future revision of this document.

Data Item

A data item is a resource that is a member of the data collection resource.

Data item representations MAY have any media type. However, a data collection MAY restrict the media types it accepts for publication. In this case, the form in the data collection representation for creating data items MUST list the acceptable media types using form fields with name <urn:TBD#accept>.

The representations of the data items MAY link back to the data collection resource using the "collection" link relation type [RFC6573].

3. Interaction Model

The interaction model consists of eight possible interactions with a data collection: discovering and reading the data collection, and creating, reading, observing, updating, deleting, and finding shared data items in the data collection.

Discovering a Data Hub

For a start, this revision of the document assumes that clients are pre-configured with a link to a data collection at some data hub.

Reading a Collection

A client can retrieve a representation of a data collection by following the pre-configured link. The representation of the data collection includes links to (and, optionally, representations of) the data items in the data collection. The representation of the data collection also includes forms for creating, updating, deleting, and finding data items.

Creating an Item

The representation of a data collection MAY contain a form with the <urn:TBD#create> form relation type. Submitting this form with a representation in one of the acceptable media types creates a new data item in the data collection. The acceptable media types are indicated by <urn:TBD#accept> form fields.

Data hubs implementing this specification MUST offer the POST method [RFC7252] in this form. The location of the created data item is conveyed in the 2.01 (Created) response by the Location-Path and Location-Query options [RFC7252].

Reading an Item

A client can retrieve a representation of a data item by following a link with the http://www.iana.org/assignments/relation/item link relation type in the data collection representation.

Observing an Item

A client can observe a data item by following a link with the http://www.iana.org/assignments/relation/item link relation type in the data collection representation and observing the target resource as specified in RFC 7641 [RFC7641].

Updating an Item

For each data item in a data collection, the representation of the data collection MAY include a nested form with the <urn:TBD#update> form relation type. Submitting this form updates the data item to the submitted representation.

Data hubs implementing this specification MUST offer the PUT method $\left[\frac{RFC7252}{1}\right]$ in this form.

Deleting an Item

For each data item in a data collection, the representation of the data collection MAY include a nested form with the <urn:TBD#delete> form relation type. Submitting this form deletes the data item from the data collection.

Data hubs implementing this specification MUST offer the DELETE method [RFC7252] in this form.

Searching for Items

The representation of a data collection MAY contain a form with the <urn:TBD#search> form relation type. This form can be used to

find data items in the data collection. Submitting this form with a search query returns the subset of data items that match the query.

Data hubs implementing this specification MUST offer the FETCH method [RFC8132] in this form.

4. Security Considerations

TODO.

5. IANA Considerations

This document has no IANA actions.

Appendix A. Related Work

The data hub is an instance of the well-known collection pattern. As such, it might be used in places where a more specialized instance of the collection pattern is currently used, such as the CoAP Publish-Subscribe Broker [I-D.ietf-core-coap-pubsub] or the CoRE Resource Directory [I-D.ietf-core-resource-directory]. This section shows how these two applications might be implemented with a data hub (without trying to replicate all of their features in detail).

A.1. CoAP Publish-Subscribe

CoAP Publish-Subscribe [I-D.ietf-core-coap-pubsub] provides means for resource-constrained sensor and actuator nodes to publish and receive data without having to be available at the same time. The basic operation involves clients called "publishers" updating "topic" resources at a server called the "broker" and clients called "subscribers" observing these resources (Figure 2).

Figure 2: CoAP Publish-Subscribe

A broker might be implemented as a data hub by creating the topics as resources on the data hub server and linking to these from the data collection resource (Figure 3). Hypermedia controls in the data collection representation enable publishers to create, update, and delete topics as well as subscribers to read or observe these topics.

A.2. CoRE Resource Directory

A CoRE Resource Directory [I-D.ietf-core-resource-directory] hosts descriptions of resources held on other servers, allowing lookups to be performed for those descriptions. The descriptions are encoded as links in CoRE Link Format [RFC6690]. The links are annotated with a

variety of link attributes providing the type of and hints about the linked resources.

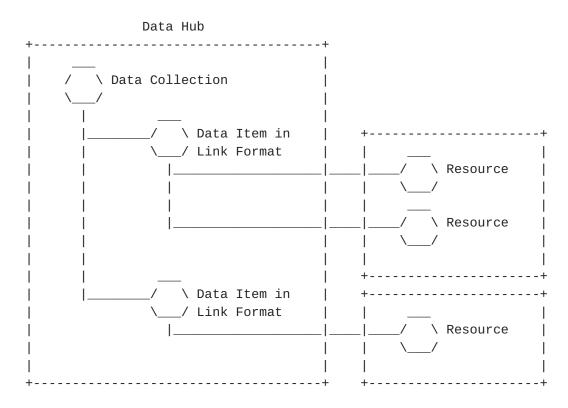

Figure 4: A Data Hub Storing Link Format Items

A data hub might be used to store these resource descriptions. Each resource description becomes a data item in a data collection (Figure 4). A specialized interface for querying the cumulative set of stored links might be provided separately.
