IPv6 Hop-by-Hop Options Processing Procedures

Abstract

This document specifies procedures for how IPv6 Hop-by-Hop options are processed. It modifies the procedures specified in the IPv6 Protocol Specification (RFC8200) to make processing of IPv6 Hop-by-Hop options practical with the goal of making IPv6 Hop-by-Hop options useful to deploy and use in the Internet. When published, this document updates RFC8200.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 4 December 2021.

Table of Contents

1. Introduction

This document specifies procedures for how IPv6 Hop-by-Hop options are processed. It modifies the procedures specified in the IPv6 Protocol Specification (RFC8200) to make processing of IPv6 Hop-by-Hop options practical with the goal of making IPv6 Hop-by-Hop options useful to deploy and use in the Internet.

When published this document updates [RFC8200].

The current list of defined Hop-by-Hop options can be found at [IANA-HBH].

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Terminology

This document uses the following loosely defined terms:

* Forwarding Plane: IPv6 hosts exchange user data through the forwarding plane. User data is processed by its recipient (i.e., an IPv6 host). User data can traverse intermediate nodes (i.e., routers) between its source and its destination. These intermediate nodes process metadata contained in packet headers. However, they do not process information contained in packet payloads.

*Control Plane: IPv6 routers exchange management and routing information with controllers. They also exchange routing information with one another. Management and routing information is processed by its recipient (i.e., an IPv6 router or controller). Management and control information can traverse intermediate nodes (i.e., routers) between its source and its destination. These intermediate nodes process metadata contained in packet headers. However, they do not process information contained in packet payloads. So, from their perspective, this information is user data.

*Fast Path: A path through a router that is optimized for forwarding packets without processing their payloads. The Fast Path may be supported by Application Specific Integrated Circuits (ASICS), Network Processor (NP), or other special purpose hardware. This is the usual processing path within a router taken by the forwarding plane.

*Slow Path: A path through a router that is capable of general purpose processing and is not optimized for any particular function. This is processing path is used for packets that require special processing or differ from assumptions made in Fast Path heuristics, or to process router control protocols used by the control plane.

NOTE: This distinct separation between hardware and software processing from [RFC6398] does not apply to all router architectures. However, a router that performs all or most processing in software might still incur more processing cost when providing special processing (aka Slow Path).

[RFC6192] is an example of how designs can separate control plane (Slow Path) and forwarding plane (Fast Path) functions.

4. Background

In the first version of the IPv6 specification, Hop-by-Hop options were required to be processed by all nodes: routers and hosts. This proved to not be practical in high speed routers due to several factors, including:

*Inability to process the hop-by-hop options at wire speed on the Fast Path.

*Hop-by-Hop options would be sent to the Slow Path. This could could degrade the a router's performance and it's ability to process important control traffic.

*A mechanism that forces packets from any source to the routers "Slow Path" could be exploited as a Denial of Service attack against the router.

* Packets could contain multiple Hop-by-Hop options making the previous issues worse by increasing the complexity required to process them.

When the IPv6 Specification was updated and published in July 2017 as [RFC8200], the procedures relating to hop-by-hop options were as follows:

> Extension headers (except for the Hop-by-Hop Options header) are not processed, inserted, or deleted by any node along a packet's delivery path, until the packet reaches the node (or each of the set of nodes, in the case of multicast) identified in the Destination Address field of the IPv6 header.
>
> The Hop-by-Hop Options header is not inserted or deleted, but may be examined or processed by any node along a packet's delivery path, until the packet reaches the node (or each of the set of nodes, in the case of multicast) identified in the Destination Address field of the IPv6 header. The Hop-by-Hop Options header, when present, must immediately follow the IPv6 header. Its presence is indicated by the value zero in the Next Header field of the IPv6 header.
>
> NOTE: While [RFC2460] required that all nodes must examine and process the Hop-by-Hop Options header, it is now expected that nodes along a packet's delivery path only examine and process the Hop-by-Hop Options header if explicitly configured to do so.

The changes meant that an implementation complied with the IPv6 specification even if it did not process hop-by-hop options, and that it was expected that routers would add configuration information to control which hop-by-hop options they would process.

Unfortunately, this did not improve the processing of Hop-by-Hop options and did not significantly improve deployment and use in the Internet. Essentially, it only documented how they were being used in the Internet at the time RFC8200 was published.

The main issues remain:

* Routers are commonly configured to drop transit packets containing hop-by-hop options that would have be processed in the Slow Path. This behavior is seen as protecting against a denial of service attack on the router. This is discussed in [I-D.ietf-v6ops-ipv6-ehs-packet-drops].

* Allowing multiple hop-by-hop options in a single packet makes it even more expensive in router resources to process these packets. It adds complexity to the number of permutations that might need to be processed.

* Any mechanism that can be used to force packets into the router's Slow Path can be exploited as a denial of service attack on a

transit router by saturating the resources needed for router management protocols (e.g., routing protocols, network management protocols, etc.) that may cause the router to fail. This issue for the Router Alert option, which intentionally places packets on the Slow Path, is discussed in [RFC6398]. Section 3 of that RFC includes a good summary:

"In a nutshell, the IP Router Alert Option does not provide a convenient universal mechanism to accurately and reliably distinguish between IP Router Alert packets of interest and unwanted IP Router Alert packets. This, in turn, creates a security concern when the IP Router Alert Option is used, because, short of appropriate router-implementation-specific mechanisms, the router Slow Path is at risk of being flooded by unwanted traffic."

There has been research that discussed the general problem with dropping packets containing IPv6 extension headers, including the Hop-by-Hop Options header. For example [Hendriks] states that "dropping all packets with Extension Headers, is a bad practice", and that "The share of traffic containing more than one EH however, is very small. For the design of hardware able to handle the dynamic nature of EHs, we therefore recommend to support at least one EH".

This document defines a set of procedures for the hop-by-hop option header that make the processing of hop-by-hop options practical in modern transit routers.

5. Hop-by-Hop Header Processing Procedures

This section describes several changes to [RFC8200].

5.1. Hop-by-Hop Options Per Packet

The Hop-by-Hop Option Header as defined in Section 4.3 of [RFC8200] is identified by a Next Header value of 0 in the IPv6 header. Section 4.1 of [RFC8200] requires a Hop-by-Hop Options header to appear immediately after the IPv6 header. [RFC8200] also requires that a Hop-by-Hop Options header can only appear once in a packet.

The Hop-by-Hop Options Header as defined in [RFC8200] can contain one or more Hop-by-Hop options. This document updates [RFC8200] that a node MUST process the first Option in the Hop-by-Hop Header in the Fast Path and MAY process additional Hop-by-Hop Options if configured to do so. The motivation for this change is to simplify the processing of Hop-by-Hop options in the Fast Path.

Nodes creating packets with a Hop-by-Hop option headers SHOULD include a single Hop-by-Hop Option in the packet and MAY include more based on local configuration.

If there are more than one Hop-by-Hop options in the Hop-by-Hop Options header, the node MAY skip the rest of the options without

having to examine these options using the "Hdr Ext Len" field in the Hop-by-Hop Options header. This field specifies the length of the Option Header in 8-octet units. The additional options do not need to be processed or verified.

5.2. Hop-by-Hop Headers Processing

Nodes that implement a differentiation between a Fast Path and a Slow Path MUST process all (with one exception noted below) Hop-by-Hop options in the Fast Path. The one exception to this is the Router Alert Option [RFC2711]. See Section 5.3 for discussion of the Router Alert.

If the node can not process an option in the Fast Path, it MUST behave as if it does not recognize the Option Type (as described in the next paragraph).

Section 4.2 of [RFC8200] defines the Option Type identifiers as internally encoded such that their highest-order 2 bits specify the action that must be taken if the processing IPv6 node does not recognize the Option Type. The text is:

00 - skip over this option and continue processing the header.

01 - discard the packet.

10 - discard the packet and, regardless of whether or not the packet's Destination Address was a multicast address, send an ICMP Parameter Problem, Code 2, message to the packet's Source Address, pointing to the unrecognized Option Type.

11 - discard the packet and, only if the packet's Destination Address was not a multicast address, send an ICMP Parameter Problem, Code 2, message to the packet's Source Address, pointing to the unrecognized Option Type.

This document modifies this behaviour for the "10" and "11" values that the node MAY send an ICMP Parameter Problem, Code 2, message to the packet's Source Address, pointing to the unrecognized Option Type. The modified text for "10" and 11" values is:

10 - discard the packet and, regardless of whether or not the packet's Destination Address was a multicast address, MAY send an ICMP Parameter Problem, Code 2, message to the packet's Source Address, pointing to the unrecognized Option Type.

11 - discard the packet and, only if the packet's Destination Address was not a multicast address, MAY send an ICMP Parameter Problem, Code 2, message to the packet's Source Address, pointing to the unrecognized Option Type.

The motivation for this change is to loosen the requirement to send ICMPv6 Parameter Problem messages to simplify what the router needs to do in the Fast Path when it does not recognize the Option Type.

When an ICMP Parameter Problem, Code 2, message is delivered to the source, the source can become aware that at least one node on the patch has failed to recognize the option.

5.3. Router Alert Option

The Router Alert option [RFC2711] purpose is to tell the node that the packet needs additional processing on the Slow Path.

The Router Alert option includes a two octet Value field that describes the protocol that is carried in the packet. The current values can be found in the IANA Router Alert Value registry [IANA-RA].

DISCUSSION

> The Router Alert Option is a problem since it's function is to do what this specification is proposing to eliminate, that is, process the packet in the Slow Path. One approach would be to deprecate it as it's usage appears to be limited and packets containing Hop-by-Hop options are frequently dropped. Deprecation would allow current implementations to continue and it's use could be phased out over time.
>
> The authors current thinking is that the Router Alert function may have reasonable potential use for new functions that have to be processed in the Slow Path. We think that keeping it as the single exception for Slow Path processing with the following restrictions is a reasonable compromise to allow future flexibility. These are compatible with Section 5 of [RFC6398].

A Fast Path implementation SHOULD verify that a Router Alert contains a protocol, as indicated by the Value field in the Router Alert option, that is configured as a protocol of interest to that router. A verified packet SHOULD be sent on the Slow Path for processing [RFC6398]. Otherwise, the router implementation SHOULD forward within the Fast Path (subject to all normal policies and forwarding rules). As specified in [RFC2711] the top two bits of Option Type for the Router Alert option are always set to "00" indicating the node should skip over this option and continue processing the header in this case.

Implementations of the IP Router Alert Option SHOULD offer the configuration option to simply ignore the presence of "IP Router Alert" in IPv4 and IPv6 packets" [RFC6398].

A node that is configured to process a Router Alert option using the Slow Path MUST protect itself from infrastructure attack that could result from processing on the Slow Path. This might include some

combination of access control list to only permit from trusted nodes, rate limiting of processing, or other methods [RFC6398].

5.4. Configuration

Section 4 of [RFC8200] allows for a router to control it's processing of IPv6 Hop-by-Hop options by local configuration. The text is:

> NOTE: While [RFC2460] required that all nodes must examine and process the Hop-by-Hop Options header, it is now expected that nodes along a packet's delivery path only examine and process the Hop-by-Hop Options header if explicitly configured to do so.

A possible approach to implementing this is to maintain a lookup table based on Option Type of the IPv6 options that are supported in the Fast Path. This would allow for a node to quickly determine if an option is supported and can be processed. If the option is not supported, then the node processes it as described in Section 5.2 of this document.

A node configured not to process HBH options, MUST drop the packet if the top two bits of the Option Type field of the first HBH option is non-zero.

The actions of the lookup table SHOULD be configurable by the operator of the router.

6. New Hop-by-Hop Options

Any new IPv6 Hop-by-Hop option designed in the future should be designed to be processed in the Fast Path. New options MUST NOT be defined that require Slow Path processing. New Hop-by-Hop options SHOULD have the following characteristics:

* Straight forward to process. That is, they should be designed to keep the time to process low.

* Fixed size in 8-octet units. Specifically any new Hop-by-Hop options should not be variable size that could extend beyond what can be executed in the Fast Path.

Any new Hop-by-Hop option that is standardized that does not meet these criteria needs to explain in detail in its specification why this can not be accomplished and that there is a reasonable expectation that it can be proceed in most Fast Path implementations.

7. IANA Considerations

There are no actions required for IANA defined in this document.

8. Security Considerations

Security issues with IPv6 Hop-by-Hop options are well known and have been documented in several places, including [RFC6398], [RFC6192], and [I-D.ietf-v6ops-ipv6-ehs-packet-drops]. The main issue, as noted in Section 4, is that any mechanism that can be used to force packets into the router's Slow Path can be exploited as a denial of service attack on a transit router by saturating the resources need for router management protocols (e.g., routing protocols, network management protocols, etc.) that may cause the router to fail. Due to this it's common for transit routers to drop packets with Hop-by-Hop options headers.

While Hop-by-Hop options are not required to be processed in the Slow Path, the Router Alert options is designed to do just that.

This document changes the way Hop-by-Hop options are processed in several ways that significantly reduces the attack surface. These changes include:

* All Hop-by-Hop options (with one exception) must be processed in the Fast Path. Only one HBH Option MUST be processed and additional HBH Options MAY be processed based on local configuration.

* Only the Router Alert option can be processed in the Slow Path, and the router must be configured to do so.

* Added criteria to allow control over how Router Alert options are processed and that a node configured to support these options must protect itself from attacks using the Router Alert.

* Limited the default number of Hop-by-Hop options that that can be in a packet to a single Hop-by-Hop option.

* Additional Hop-by-Hop options MAY be included, based on local configuration. Although nodes only process these additional Hop-by-Hop Options if configured to do so.

* Added restrictions to any future new Hop-by-Hop options that limit their size and computational requirements.

The authors believe that these changes significantly reduces the security issues relating to IPv6 Hop-by-Hop options and will enable them to be used safely in the Internet.

9. Acknowledgments

Helpful comments were received from Brian Carpenter, Ron Bonica, Ole Troan, Mark Heard, Tom Herbert, [your name here], and other members of the 6MAN working group.

10. Change log [RFC Editor: Please remove]

draft-hinden-6man-hbh-processing-01, 2021-June-2:

- *Expanded terminology section to include Forwarding Plane and Control Plane.
- *Changed draft that only one HBH Option MUST be processed and additional HBH Options MAY be processed based on local configuration.
- *Clarified that all HBH options (with one exception) must be processed on the Fast Path.
- *Kept the Router Alert options as the single exception for Slow Path processing.
- *Rewrote and expanded section on New Hop-by-Hop Options.
- *Removed requirement for HBH Option size and alignment.
- *Removed sections evaluating currently defined HBH Options.
- *Added content to the Security Considerations section.
- *Added people to the acknowledgements section.
- *Numerous editorial changes

draft-hinden-6man-hbh-processing-00, 2020-Nov-29:

- *Initial draft.
