MEGACO Control Association State Machine
[draft-hss-megaco-control-association-state-machine-00.txt](#)

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC2026](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsolete by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at

<http://www.ietf.org/ietf/lid-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at

<http://www.ietf.org/shadow.html>.

Abstract

This document captures the description and interpretation of all the functional procedures and the related procedural parameters, pertaining to MG-MGC control association, as described in the MEGACO protocol.

It suggests the various states, the MG and MGC state machines goes through, during the life cycle of such an association. It goes on to

Vikas, Vivek, Shiv, Prashant

1

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

describe the various inputs each association state of an MG/MGC may deal with and how the MG/MGC may react towards them.

This document should be read as the supplement to the base protocol.

1. Scope

This document puts into words, the interpretation the authors have, after studying the MEGACO RFC, Implementation Guides and discussions in the MEGACO mailing list, Annex L and the manner in which the control association state machine of MG and MGC work while executing the respective control association procedures.

There is still a certain amount of lack of clarity regarding the topic of control associations in MEGACO perspective as a whole. So to help arrive at some kind of conclusion, the authors have made some assumptions about these unclear aspects of the protocol. Changes in these assumptions may affect the overall interpretation of this topic. Nevertheless the authors have tried their utmost to preserve the existing description of the protocol. The authors have also taken into account various converging assumptions, which were discussed, extensively on the mailing list.

3. Abbreviations

This recommendation defines the following terms.

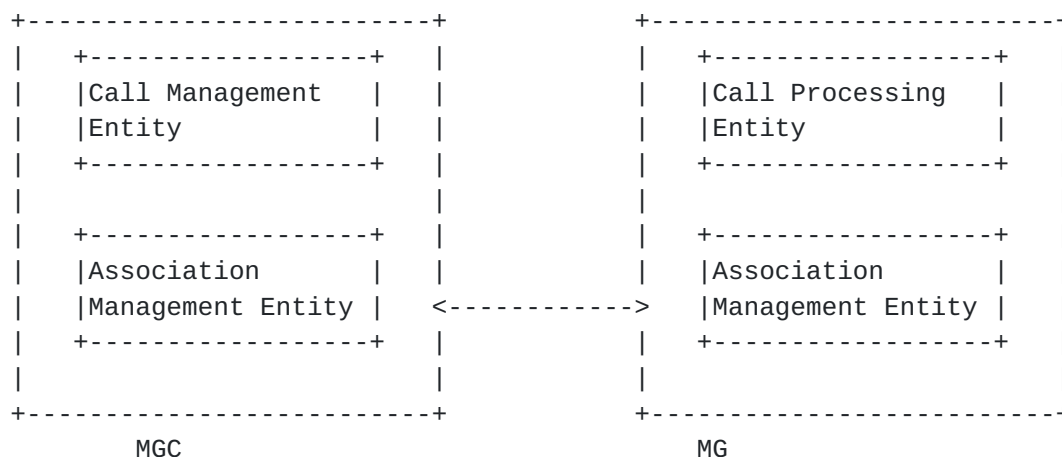

GW	GateWay
IANA	Internet Assigned Numbers Authority
IP	Internet Protocol
MG	Media Gateway
MGC	Media Gateway Controller
NM	Network Management

4. Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119](#).

5. Control Association Overview

A control association can be defined as the logical session between two key entities of the decomposed gateway architecture viz., MG and MGC. MEGACO protocol has defined a set of control association procedures between these two entities to achieve the distributed call control functionality. The control association functionality has been visualized as a disjoint set of procedures independent of the call processing/management activity. However any change (permanent or transient) in the state of the control association between MG and MGC may or may not affect the call-related aspects both at MG and MGC.

6. Assumptions

- (1) Peer Entities shall be identified based on the MID field in the message header field of the protocol message.
- (2) Primary and secondary MGCs may be supporting different versions and gateway service profiles.
- (3) Service Change command with method as `ôRESTARTö` on `ROOT` terminations indicates that all terminations are in service, by default.
- (4) Synchronization between redundant MGs and that between redundant MGCs is outside the scope of the MEGACO protocol.
- (5) Since the Mid should not change during the course of the control association, MGs running in redundant configuration must have same MIDs.

- (6) MGCs running in redundant configuration may or may not have same MIDs.
- (7) Secondary MGCs being provisioned at MG may or may not be running in the redundant configuration.
- (8) `Service Change Reason` parameter can be understood as the qualifier to the information that the `method` field conveys while indicating the change in the control association through the service change command.
- (9) The `Service Change Address` and `MGCIdToTry` parameters are only applicable on ROOT termination. When sent in a service change command would convey the transport address to which future communication should be made.
- (10) A MG is pre-provisioned by a management mechanism outside the scope of this protocol with a Primary and (optionally) an ordered list of Secondary MGCs.

The pre-provisioning of MGCs at MG reveals all the transport parameters of the specified MGCs, at which MG would initially try to create the logical session with one of them. The MIDs of the respective MGCs may or may not be configured along with the transport parameters.

However, MGC need not be provisioned with the list of MGs, from which the control associations request can be received during the start up phase. The controlled MGs would be identified by their MIDs, retrieved from the first service change command being received from each of them. The MID of the respective MGs must not change during the life cycle of the control association.

7. Definitions related to Control Association

The terms mentioned below are important and are to be kept in mind while reading the document. These should be referred to as and when required.

- A. Cold Start: It is defined as the fresh start of the Media Gateway. All the terminations would be assumed to be in-service by default. All the terminations would be present in the NULL context. In other words, no active calls would be running over any of the associated terminations present in the specified control association.
- B. Planned Switchover: It is defined as a planned activity being initiated either by MG or MGC application or the NM entity, which triggers the generation of Service Change command from the entity which is going out-of-service and informs about the switchover to a redundant entity.
- C. Transparent Switchover: It is defined as an activity wherein the MGC or MG does not come to know about the redundant takeover that happened on the other entity involved in the control association, as the transport parameters of the affected entity (MG or MGC) have been retained.
- D. Unplanned Switchover: It is defined as an unplanned activity occurring at MG, which caused it to go abruptly out-of-service. Moreover due this activity, redundant MG has taken over the control and it sends the Service Change command. Here there would not be any protocol message that was generated from the MG that went down.
- E. Warm Redundancy: It is defined as the switchover operation from an active to a standby entity, wherein all the existing calls on the failed entity have been lost, although a new entity (standby) has taken over the control association. Both MG and MGC can have this kind of implementation.
- F. Hot Redundancy: It is defined as the switchover operation between an active and a standby entity, wherein all the existing calls have survived over the standby one, even though the new entity (standby) has taken over the control association. All the call states were preserved. Both MG and MGC can have this kind of implementation.
- G. Cold Boot: It is defined as the boot operation in which MG was able to preserve the statically provisioned data by NM as well as

however all the active contexts or calls were lost due to some internal failure.

H. Warm Boot: It is defined as the boot operation in which MG was able to preserve the static provisioned data by NM as well as the dynamic configuration data provided by MGC in NULL context.

In Warm Boot, all the active contexts or calls were survived at the MG, however some of the transient transactions are lost.

I. Message Identifier (MID): This field is an identifier (either the transport address or just a logical identifier) that reveals the identity of the entity, which is originating the protocol message. It is the mandatory part of the every protocol message that is exchanged between MG and MGC.

8. The Service Change Command

MEGACO protocol defines all the control association procedures using a Service Change command on ROOT termination. Each such command would encapsulate a set of control parameters that would be utilized while executing the related procedures. A service change command on ROOT governs the change in the state of the control association in terms of the change in either the communication status between MG-MGC or the change in the existing call states.

It is worth noting that a Service Change with termination ID as ALL or 0 just means that terminations in the originating entity have undergone a state change in the service-state. This may impact the existing calls that are active over the specified terminations. However there is no change in the state of the control association.

The control parameters pertaining to a service change command are listed below.

- A. Service Change Method.
- B. Service Change Reason.
- C. Service Change Profile.
- D. Service Change Version.
- E. Service Change Address.
- F. Service Change MGCIdToTry.
- G. Service Change Delay.
- H. Service Change Timestamp.

Vikas, Vivek, Shiv, Prashant

8

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

Of all the above parameters, the service change method is the main

attribute that primarily dictates the behavioral change in the state of a control association. The other parameters, which are the part of the service change command, help the remote entity to execute the relevant protocol-defined procedures with respect to the state change in the control association. For instance, in case of command issued with `DISCONNECTED` method from MG, it is conveyed to MGC that the MG was temporarily disconnected with MGC. Here MGC may infer that there may be some synchronization problem between the two and an AUDIT command may be issued.

The `service change reason`, if specified, should be looked into to determine the severity of change in the states of the calls being realized by MG and then act accordingly.

The `service change timestamp`, if specified, conveys the exact time when the service change command was issued. This would help the receiving entity in making decisions irrespective of the transport delay.

8.1. Usage of Service Change Method

The `Service Change Method` parameter on ROOT specifies the change in the control association between MG and MGC. The change in service may be because of either of the following functional changes.

Note that the Service Change Reason conveys the gravity of the change in call states, as and when required.

These two aspects can be understood more clearly as one goes through the interpretation of different methods defined in the protocol.

a. Graceful:

1. This method can only be sent from MG to MGC. It indicates that the MG will be taken out of service after the specified Service Change Delay.
2. The established connections or calls over the individual terminations are not yet affected.
3. After the specified delay, all the calls would be terminated abruptly, and all the terminations would be moved into the null

Vikas, Vivek, Shiv, Prashant

9

INTERNET-DRAFT

MEGACO Control Association
Procedures and State Machine

August 2001

context at MG. The controlling MGC will not send any SUBTRACT command to MG and clear all the call contexts at its end.

4. The "graceful" with delay NULL means that MG would terminate the control association AFTER all the call contexts are cleared.

5. In either of the above cases, the MGC should refrain from establishing new calls during the course of the graceful shutdown and should try to clear the existing call contexts gracefully.

b. Forced:

1. This method can either be sent from MG to MGC or vice versa.

2. It indicates that the originating entity (MG/MGC) was taken abruptly out of service and any established connections or calls active over the associated terminations were lost, consequently all the terminations at its end were moved to null context.

3. The receiving entity (MGC/MG) is responsible for cleaning up the call contexts at its end.

c. Restart:

1. This method can be sent from MG to MGC or vice versa.

When sent from the MG to the MGC,

2. At COLD start, it indicates that the MG has already come into service afresh. All the terminations are assumed to be in service.

3. If non-zero delay is specified, it signifies that although the MG is capable of communicating with the controlling MGC, the service or the call-carrying capability would be restored on the physical terminations, associated with "ROOT" termination, AFTER the specified delay.

When sent from the MGC to the MG,

4. It indicates the MGC wants MG to restart.

Vikas, Vivek, Shiv, Prashant

10

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

5. If non-zero delay is specified, it signifies that the service or the call-carrying capability would be restored on the physical terminations, associated with "ROOT" termination, AFTER the specified delay.

6. In case of warm boot or cold boot, it indicates change in the protocol version supported by the remote. In this case, the already existing calls at MG may or may not be retained.

d. Disconnected:

1. This method can only be sent from MG to MGC.
2. This method indicates that the MG lost communication with the controlling MGC either because of its transient failure, which was subsequently restored or MG detects failure of its controlling MGC and tries to contact it again.
3. The transient failure may be because of:
 - Failures of the underlying transport or there was some change in the transport parameters of MG.
 - If there is some call-state loss at MG.
 - Switchover (either planned or unplanned) to standby MG. Here the standby MG generates this method.
4. In either of the above scenarios, the MGC may audit the MG to synchronize its state.

e. Handoff:

1. This method can either be sent from MG to MGC or vice versa.

When sent from the MGC to the MG,

2. This method indicates that the MGC is going out of service and a control association must be established with the new MGC.

However sent from the MG to the MGC,

Vikas, Vivek, Shiv, Prashant

11

INTERNET-DRAFT

MEGACO Control Association
Procedures and State Machine

August 2001

3. This indicates that the MG is attempting to establish a new control association in accordance with a Handoff received from the MGC with which it was previously associated.
4. The above operation should be transparent to the MG application.
5. In this case, MGC must audit the requesting MG to resynchronize

its state, in the absence of which MG assumes that MGC has failed and start trying secondary ones.

f. Failover:

1. This method can only be sent from MG to MGC.
2. When sent from the MG, which is going down, this method indicate the primary MG is out of service and a secondary MG would be taking over.
3. Otherwise, this method reveals that MG detects the failure of its controlling MGC and is now trying the secondary MGC to re-establish the control association.
4. In either of the above cases, the already existing calls at MG may or may not be retained.

Vikas, Vivek, Shiv, Prashant

12

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

The valid combinations of the Method vis- -vis other Service change parameters have been captured in the following table:

Method/ Parameters	DELAY	DIRECTION	VERSION	PROFILE	SVC ADDR	MGCIdToTry
RESTART	A	MG->MGC	A	A	A	NA
FORCED	NA	MG->MGC MGC->MG	NA	NA	NA	NA
GRACEFUL	A	MG->MGC	NA	NA	NA	NA

DIS-									
CONNECTED	NA	MG->MGC	NA		NA		A		NA
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+									
FAILOVER	NA	MG->MGC	A		A		NA		NA
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+									
HANDOFF	NA	MGC->MG	A		A		NA		A
		MG->MGC							
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+									

A - Allowed
NA- Not Allowed

9. Overview of Protocol Control Association Procedures

As already mentioned, protocol has defined a set of procedures to address the various aspects of control association between MG and MGC. Apart from this, some guidelines have been laid for initial provisioning of MG before the actual control association is established between MG and MGC.

All the control association procedures that have been discussed in the protocol cater to a set of scenarios. Hence the relevant procedures have been categorized into different phases, depending on the behavioral changes the control association undergoes during its life cycle, for all the respective scenarios. This categorization would form the basis on which the complete state machine design of the MG-MGC control association would rely upon.

Vikas, Vivek, Shiv, Prashant

13

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

9.1. Phases in a Control Association Life Cycle

Further based on whatever protocol has defined, the life cycle of a control association can be divided into the following phases.

1. Association Inactive Phase.
2. Association Restart Phase.
3. Association Active Phase.
4. Association Shutdown Phase.
5. Association Switchover Phase.

- 1) Inactive Phase: During this phase of operation, both MG and MGC would just have the necessary pre-provisioned data (specifically the transport parameters) and they are waiting for a trigger from the application to initiate the control association related procedures.

- 2) Restart Phase: During this phase of operation, the control association between MG and MGC is restarted between the concerned MG and the MGC.

The following scenarios and the corresponding procedures can be addressed in this phase of operation.

- . A control association between the concerned MG and MGC is initiated from MG at its Cold start. No calls are present at the moment.

Method: RESTART from MG.

Reason: Cold Boot or Service Restored.

- . MG wants to change its protocol version. The calls may or may not get affected (call states change would be decided by `Service Change Reason`, if present).

Method: RESTART from MG.

Reason: Warm Boot, Cold Boot or Service Restored.

- . MGC wants to change its protocol version. The calls may or may not get affected (call states change would be conveyed to by `Service Change Reason`, if present).

Method: RESTART from MGC.

Reason: Warm Boot, Cold Boot or Service Restored.

Vikas, Vivek, Shiv, Prashant

14

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

- . MGC wants to initiate a reboot operation at MG due to its own failure or in case of version change at its end. The corresponding service change request from MGC may be generated only if the MG was already registered with the former.

Method: RESTART from MGC.

Reason: Warm Boot, Cold Boot.

- 3) Active Phase: During this phase of operation, MG-MGC control association is alive and normal protocol commands get exchanged across the two entities as defined in the protocol. In this phase of operation, MG may exchange the control association command (service change on ROOT) intending to resynchronize the states of the terminations engaged in the association or to convey about the future behavior of the control association.

Note that the `Service Change` command on ROOT is not allowed

from MGC for the state synchronization with the peer. The following two possibilities may arise in this phase of operation.

The following control association scenarios and the corresponding procedures can be addressed in this phase of operation.

- . If there is a transient failure at MG, either due to a problem in the underlying transport layer, or there was a transparent switchover at MG but it was recovered subsequently.

Method: DISCONNECTED from MG.

Reason: Cold Boot or Warm Boot.

- . If there is going to be a service shutdown at MG after some planned duration, MG may initiate a service change command to the peer MGC to convey the same information so that the latter may act accordingly. However, the existing association is not affected at all.

Method: GRACEFUL from MG.

Reason: None.

- . If there is a planned switchover at MG to a standby entity and the new entity was realizing either Warm or Hot Redundancy.

Method: DISCONNECTED from MG.

Reason: Cold Boot or Warm Boot.

Vikas, Vivek, Shiv, Prashant

15

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

- 4) Association Switchover Phase: This phase can be visualized as the activity involved in bringing the control association back to the active phase by switching over to a different entity. This switchover to a different remote may occur either implicitly (peer failure detection locally) or explicitly (through failure notification from remote)

The following control association scenarios and the corresponding procedures can be addressed in this phase of operation.

- . MGC detects the failure of its controlled MG and it waits for a service change request from MG (either it may be active or the standby), to re-establish the control association.

Method: MGC expects either RESTART or DISCONNECTED.

Reason: Cold Boot or Warm Boot.

- . MGC receives the failure indication from its controlled MG and

it waits for a re-registration request from either the active or the standby MG afterwards.

From active MG

Method: FAILOVER.

Reason: MG Impending Failure.

Subsequently from standby MG

Method: RESTART or DISCONNECTED.

Reason: Cold Boot or Warm Boot.

- . MG detects the failure of its controlling MGC and it tries the secondary MGCs in order, to re-establish the control association.

Method: FAILOVER from MG.

Reason: MGC Impending Failure.

- . MG detects the failure of its controlling MGC and the control association is also not established with secondary MGCs and the failed one is attempted again.

Method: DISCONNECTED from MG.

Reason: MGC Impending Failure.

Vikas, Vivek, Shiv, Prashant

16

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

- . MG tries to register with the handed-off MGC as redirected by its controlling MGC to re-establish the control association with the newly specified MGC.

Method: HANDOFF from MG.

Reason: MGC Directed Change.

- 5) Association Shutdown Phase: This phase can be visualized as the period during which the originating entity conveys to the remote entity (MG or MGC) about its own failure. Additionally, the sending entity may indicate that another entity would come up to take up the control of the specified association.

The following control association scenarios and the corresponding procedures can be addressed in this phase of operation.

- There is a planned switchover activity being initiated at MG due to a local failure or for maintenance reasons and the same is conveyed to MGC.

Method: FAILOVER from MG.

Reason: MG Impending Failure.

- There is a planned switchover activity being initiated at MGC due to a local failure or for maintenance reasons and the same is conveyed to MG.

Method: HANDOFF from MGC.

Reason: MGC Impending Failure.

- There is a forced shutdown at MG or MGC and the specified entity wishes to convey this information to its peer. Both MG and MGC would terminate all the active calls at their ends.

Method: FORCED from MGC or MG.

Reason: None.

9.2. Control Association States Description

The input triggers to the state machine would be extracted from the identified scenarios in the above section and the different states inside the state machine are determined from the identified phases.

Vikas, Vivek, Shiv, Prashant

17

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

The states, which have been designed in both MG and MGC state machines, maps one-to-one on the phases explained earlier and are listed as follows:

1. Restart In Progress.
2. Association In Service.
3. Switchover In Progress.
4. Shutdown In Progress.
5. Inactive.

The list of various inputs to the state machine is as follows.

1. Cold Start at MG.
2. Registration Response from MGC.
3. Forced Shutdown at MG.
4. Graceful Shutdown at MG.
5. Failover at active MG.
6. Redundant Takeover at standby MG.
7. Peer Failure Detection at MG.
8. Transport Parameters Change at MG.
9. Restart From MGC.
10. Handoff at Active MGC.
11. Peer Failure Detection at MGC.

12. Forced Shutdown at MGC.

10. MG State Machine

This section gives the actual protocol procedures that must be followed or the actual protocol commands that must be exchanged when the expected input triggered in either of the defined states. With every call flow we will also identify, what are the possible inputs that can be triggered in these states.

Vikas, Vivek, Shiv, Prashant

20

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

10.1. INACTIVE STATE

10.1.1. Cold Start from MG application

Input parameters:

- Service change delay.
- Service Change Address.
- Service Change Version.
- Service Change Profile.

10.1.1.1. Steps

- 1) Start the restart avalanche timer.
- 2) On expiry of the restart avalanche timer, send the service change request command with method as RESTART, reason as SERVICE RESTORED and the other specified parameters.
- 3) In addition to the generation of Service Change command, start the Restart Delay timer, if present.

10.1.1.1. New State

RIP (RESTART IN PROGRESS)

10.1.2. Redundant Takeover at standby MG

Input parameters:

- Service Change Address.
- Service Change Reason.

10.1.2.1. Steps

- 1) Send the service change request command with method as DISCONNECTED and the other specified parameters.

10.1.2.1. New State

AIS (ASSOCIATION IN SERVICE)

10.2. RIP (RESTART IN PROGRESS)

Vikas, Vivek, Shiv, Prashant

21

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

10.2.1. Registration Response from Peer

Input parameters: None

10.2.1.1. Steps

- 1) During the registration, if all the parameters were accepted by MGC, it replies back with the successful response.
 - a) If the delay was specified in the service change delay, then the state remains same. On expiry of the restart delay, the state is changed to AIS (ASSOCIATION IN SERVICE).
 - b) If the delay was not specified, the state is immediately changed to (AIS) ASSOCIATION IN SERVICE.
- 2) If Service change address present in the service change command response from peer, modify the address of the MGC to send all the subsequent requests to MGC on the newly specified address. Association State in this case again depends upon the service change delay parameter sent in the request as described in step 1.
- 3) If the ServiceChangeMgcId is present in the service change command response from peer. Then,
 - a) MG sends the service change command to MGC specified in the ServiceChangeMgcId with the same parameters.
 - b) This procedure continues till the registration request

is accepted by the new MGC.

4) If the Protocol Version is present in the Service change response.

a) If MG complies with the version received in the service change response, state changes would be as described in step 1.

b) If the MG is not able to comply with the version received in the service change response, it tries the secondary MGCs with the same service change

Vikas, Vivek, Shiv, Prashant

22

INTERNET-DRAFT

MEGACO Control Association
Procedures and State Machine

August 2001

parameters till the registration request is accepted by any of the configured MGCs.

10.2.2. Forced Shutdown from MG application

Input parameters: None

10.2.2.1. Steps

1) Clear all the call contexts forcefully.

2) Send Service Change command to the controlling MGC with method as FORCED.

10.2.2.2. New State

INACTIVE

10.2.3. Graceful Shutdown from MG application

Input parameters:

- Service Change Delay

10.2.3.1. Steps

1) If the Graceful delay is less than the Restart delay, then stop the Restart delay timer, then send the service change request to MGC with method as FORCED. The new state becomes INACTIVE.

2) If the Graceful delay is more that the Restart delay, send the service change request to MGC with method as GRACEFUL and delay as specified in the input parameters. The state remains unchanged.

10.2.4. Failover at active MG

The MG Failover is not expected in this state. It is assumed that since there has been no call-related activity in this state.

10.2.5. Peer Failure Detection at MG

Vikas, Vivek, Shiv, Prashant

23

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

If MG detects the Failure of the MGC to which it had sent the service change request.

10.2.5.1. Steps

- 1) Send the service change command to secondary MGCs, with the same set of parameters as sent in the initial registration message to primary MGC until registration is completed.

10.2.5.2. New State

The state remains unchanged.

10.2.6. Transport Parameters Change at MG

Input parameters:

- Service Change Address

10.2.6.1. Steps

- 1) Send the service change command with method as RESTART and the specified Service Change Address.

10.2.6.2. New State

State remains same.

10.2.7. Restart from MGC

Input parameters:

- Service Change Reason

10.2.7.1. Steps

- 1) Stop the Restart Delay timer if running.

- 2) Give the indication to the MG application to restart MG, along with the received service change reason from MGC.

Vikas, Vivek, Shiv, Prashant

24

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

- 3) Once the restart operation is finished, MG generates the registration command to the same controlling MGC.

10.2.7.2. New State

State remains unchanged.

10.2.8. Handoff at current controlling MGC

Input parameters:

- Service Change MGCIIDToTry

This input trigger could be received from MGC if the control is transferred to a new MGC.

10.2.8.1. Steps

- 1) Start the restart avalanche timer to prevent the avalanche at MGC.
- 2) Send the service change request to Handed-off MGC with method as HANDOFF and reason as MGC Impending Failure.

10.2.8.2. New State

State remains unchanged.

10.2.9. Forced Shutdown at MGC

This input trigger could be received when the Restart Delay timer is running.

10.2.9.1. Steps

- 1) MG attempts to contact the next MGC on its pre-provisioned list. Implementation may start its attempts at the beginning (that was the MGC that failed), or it attempts the next remote in the configured list.

10.2.9.2. New State

RIP (RESTART_IN_PROGRESS)

10.2.10. Protocol message from Peer

Input parameters: None

10.2.10.1. Steps

- 1) If before receiving the response from MGC, MG received the protocol commands from MGC, it should reply back with the error code "Command received before restart response".
- 2) If after receiving the response from MGC, and if the delay timer is still running, and during this time a protocol command from MGC is received, that command should be Audit capability only. For any call related protocol commands like Add, Modify, it should return back an error "Service Unavailable".

10.2.11. Local Activity at MG application

Input parameters: None

10.2.11.1. Steps

- 1) If during the execution of the restart avalanche timer, a local activity is detected, then stop the restart avalanche timer
- 2) Send the service change request command with method as RESTART and reason as SERVICE RESTORED.

10.2.11.2. New State

State remains same.

10.3. AIS (ASSOCIATION IN SERVICE)

10.3.1. Forced Shutdown at MG

Input parameters: None

10.3.1.1. Steps

- 1) Terminate all the active calls contexts on its own.
- 2) Send the Service Change command to the MGC with method as FORCED.

10.3.1.2. New State

INACTIVE

10.3.2. Graceful Shutdown at MG

Input parameters:

- Service change delay

10.3.2.1. Steps

- 1) Start the delay timer for value specified in Service change delay.
- 2) Send the request to MGC with GRACEFUL method and with the specified service change delay.
- 3) Till the expiry of the service change delay, the state of MG control association remains ASSOCIATION IN SERVICE (AIS).
- 4) Delete all the call contexts abruptly after the completion of the graceful period.
- 5) If the NULL delay was specified, the control association must last for the duration of the time until all the active call contexts are cleared by MGC.

10.3.3. Failover at active MG

Input parameters: None

10.3.3.1. Steps

- 1) Send the service change request to MGC with FAILOVER method.

- 2) Since the protocol mandates that the response should go to the source address, the control association must wait for the respective replies for all pending transaction

requests.

10.3.3.2. New State

SIP (SHUTDOWN_IN_PRGS)

10.3.4. Peer Failure Detection at MG

Input parameters: None

10.3.4.1. Steps

- 1) If the MG detects a failure of its controlling MGC, it attempts to contact the next MGC on its pre-provisioned list. It starts its attempts at the beginning (Primary MGC), unless that was the MGC that failed, in which case it starts at its first Secondary MGC. It sends a Service Change message with a "Failover" method and reason as MGC Impending Failure.
- 2) All new transaction requests and the outstanding transaction responses must be queued till the MGC replies back with the transaction accept.

10.3.4.2. New state

SWIP (SWITCHOVER_IN_PRGS)

10.3.5. Transport Parameters Change at MG

Input parameters:

- Service Change Address

10.3.5.1. Steps

- 1) Send the service change command with method as DISCONNECTED and specify the new local address in the Service Change Address field of the command.

New State

Vikas, Vivek, Shiv, Prashant

28

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

State remains unchanged

10.3.6. Restart from MGC

Input parameters:

- Service Change Reason.
- Service Change Address.

10.3.6.1. Steps

- 1) Give the indication to the MG application to restart MG, along with the received service change reason from MGC.
- 2) Once the restart operation is finished, MG generates the registration command to the same controlling MGC on the newly specified service change address.

10.3.6.2. New State

RIP (RESTART IN PROGRESS).

10.3.7. Handoff at current controlling MGC

Input parameters:

- Service Change MGCIIDToTry

10.3.7.1. Steps

- 1) Start the restart avalanche timer to prevent the avalanche at MGC.
- 2) Send the service change request to Handed-off MGC with method as HANDOFF and reason as MGC Impending Failure.
- 3) Since this procedure must be transparent to the MG application, all new transaction requests and the outstanding transaction responses must be queued until the re-registration is complete.

10.3.7.2. New State

SWIP (SWITCHOVER_IN_PRGS)

Vikas, Vivek, Shiv, Prashant

29

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

10.3.8. Forced Shutdown at MGC

Input parameters: None

10.3.8.1. Steps

- 1) Give the indication to the MG application to clear all the call contexts.

- 2) Once the cleanup operation is finished at MG, it generates the registration command to either primary or secondary MGC with method as RESTART û Implementation specific.

10.3.8.2. New State

RIP (RESTART_IN_PROGRESS)

10.4. SIP (SHUTDOWN_IN_PRGS)

10.4.1. Forced Shutdown at MG

If during the Failover operation, the primary MG feels that the redundant MG entity is unable to take over the control, it can ask the primary MG to send Forced Shutdown towards its peer.

10.4.1.1. Steps

- 1) Terminate all the active calls contexts on its own.
- 2) Send the Service Change command to the MGC with method as FORCED.

10.4.1.2. New State

INACTIVE

10.4.2. Graceful Shutdown At MG

Vikas, Vivek, Shiv, Prashant

30

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

If during the Failover operation, the primary MG feels that the redundant MG entity is unable to take over the control, it can ask the primary MG to send Graceful shutdown towards its peer, to clear all the existing calls gracefully.

Input parameters:

- Service Change Delay

10.4.2.1. Steps

- 1) Start the delay timer for value specified in Service change delay.
- 2) Send the request to MGC with GRACEFUL method and with the specified service change delay.

- 3) Till the expiry of the service change delay, the state of MG control association becomes ASSOCIATION IN SERVICE (AIS).
- 4) Delete all the call contexts abruptly after the completion of the graceful period.
- 5) If the NULL delay was specified, the control association must last for the duration of the time until all the active call contexts are cleared by MGC.

10.4.2.2. New State

AIS (ASSOCIATION IN SERVICE).

10.4.3. Peer Failure Detection at MG

Input parameters: None

10.4.3.1. Steps

- 1) If during the Failover phase, if MG detects the failure of controlling MGC, this information should be conveyed to the standby entity (outside the scope of the protocol) so that any further recovery action (trying secondary MGCs) would be taken via the redundant MG.

Vikas, Vivek, Shiv, Prashant

31

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

10.4.3.2. New State

INACTIVE

10.4.4. Restart from MGC

Input parameters:

- Service Change Reason.
- Service Change Address.

10.4.4.1. Steps

- 1) Give the indication to the MG application to restart MG, along with the received service change reason from MGC. Henceforth, the standby MG would initiate the re-registration request to the same MGC on behalf of the failed one.

- 2) Once the restart operation is finished, standby MG generates the registration command to the same controlling MGC on the newly specified service change address.

10.4.4.2. New State

INACTIVE

10.4.5. Handoff from MGC

Input parameters:

- Service Change MGCIIDToTry.

10.4.5.1. Steps

- 1) Convey this information to the standby entity (outside the scope of the protocol) so that any further recovery action (trying handed-off MGCs) would be taken via the redundant MG.
- 2) Send the service change request to Handed-off MGC with method as HANDOFF and reason as MGC Impending Failure.

Vikas, Vivek, Shiv, Prashant

32

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

10.4.5.2. New State

INACTIVE

10.4.6. Forced Shutdown from MGC

Input parameters: None

10.4.6.1. Steps

- 1) Give the indication to the MG application to clear all the call contexts. Further any recovery action would be taken via the redundant MG.
- 2) Once the cleanup operation is finished at MG, the standby MG generates the registration command to either primary or secondary MGC with method as RESTART û Implementation specific.

8.4.4.2. New State

INACTIVE

10.5. SWIP (SWITCHOVER_IN_PRGS)

10.5.1. Forced Shutdown At MG

Input parameters: None

10.5.1.1. Steps

- 1) The implementation may either send the service change command to the MGC, which is being contacted at present, immediately with method as FORCED or MG may defer this message until the service change reply from the MGC is received for the current pending service change request.
- 2) All the call contexts would be cleared at MG without waiting for a SUBTRACT command from MGC.

Vikas, Vivek, Shiv, Prashant

33

INTERNET-DRAFT

MEGACO Control Association
Procedures and State Machine

August 2001

10.5.1.2. New State

INACTIVE

10.5.2. Graceful Shutdown At MG

Input parameters:

- Service Change Delay.

10.5.2.1. Steps

- 1) Buffer the Graceful Shutdown request until the MGC, which is being contacted, accepts the registration request.
- 2) Once the registration is complete, send the service change command with GRACEFUL method to the same MGC. If the delay was specified in the input, then the delay in the command should be the left-out time. New state in this case would be AIS (ASSOCIATION_IN_SERVICE).
- 3) If Handoff/Failover takes more time than the Graceful delay period, then the implementation will terminate the control association abruptly and all the call contexts would get cleared. New state in this case would be

INACTIVE.

10.5.3. Failover at active MG

Input parameters: None

10.5.3.1. Steps

- 1) Buffer the Failover request until the MGC, which is being contacted, accepts the re-registration request.
- 2) Once the re-registration is complete, send the service change command with FAILOVER method to the same MGC.

10.5.3.2. New State

Vikas, Vivek, Shiv, Prashant

11.1. RIP (RESTART_IN_PROGRESS)

11.1.1. Cold Start At MG

Input parameters:

- Service change delay.
- Service Change Address.
- Service Change Version.
- Service Change Profile.

11.1.1.1. Steps:

- 1) Examine the service change version of the received message.
- 2) If the MGC is unable to comply with the suggested version then send a Service Change Response to the MG with error 0406 Version not supported. State remains same.
- 3) If the MGC supports the suggested or lower version, send a Service Change Response to the MG the negotiated Service Change Version. Start Delay Timer and the state changes to RIP (RESTART_IN_PROGRESS). After Restart Delay expiry, state would become ASSOCIATION_IN_SERVICE.
- 4) If the MGC wishes to handoff the MG to another MGC, send a Service Change Response to the MG with Service Change MGCIdToTry [transport address of the new MGC]. State remains same

If the MGC wishes to change the Transport Address for further correspondence to be used by the MG, send a Service Change Response to the MG with Service Change Address [containing the new transport address] along with the other parameters. Change the state as per bullet 3.

11.1.2. Forced Shutdown At MG

Input parameters: None

11.1.2.1. Steps

- 1) Here there should not be any call running at MG.
- 2) After this, MGC shall wait for the next registration request from the MG going down.

Vikas, Vivek, Shiv, Prashant

Procedures and State Machine

August 2001

11.1.8.1. Steps

- 1) Stop restart delay timer if running.
- 2) Send Service Change Request to the MG Method as FORCED.

11.1.8.2. New State

INACTIVE

11.2. AIS (ASSOCIATION IN SERVICE)

11.2.1. Forced Shutdown at MG

Input parameters: None

11.2.1.1. Steps

- 1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.
- 2) After this, MGC shall wait for the next registration request from the MG going down.

11.2.1.2. New State

RIP (RESTART_IN_PROGRESS)

11.2.2. Graceful Shutdown at MG

Input parameters:

- Service change delay.

11.2.2.1. Steps

- 1) Start the delay timer for value specified in Service change delay.
- 2) Till the expiry of the service change delay, the state of

MG control association becomes ASSOCIATION IN SERVICE (AIS).

- 3) Delete all the call contexts abruptly after the completion of the graceful period.

Vikas, Vivek, Shiv, Prashant

41

INTERNET-DRAFT MEGACO Control Association
Procedures and State Machine

August 2001

- 4) If the NULL delay was specified, the control association must last for the duration of the time until all the active call contexts are cleared from MGC.

11.2.2.2. New State
State remains same.

11.2.3. Failover at active MG
Input parameters: None

- 11.2.3.1. Steps
- 1) The existing calls are not affected assuming that the standby MG would come up and take over the control of the specified association.
 - 2) Start waiting for a new service change command from the standby MG with method as DISCONNECTED and reason as COLD Boot or Warm Boot.

11.2.3.2. New State
SWIP (SWITCHOVER_IN_PROGRESS)

11.2.4. Transport Parameters Change at MG

Input parameters:
- Service Change Address.

- 11.2.4.1. Steps
- 1) The existing calls are not affected. MGC may do an audit.
 - 2) Starts sending the new protocol command request on the new address, as specified in the service change address parameter.

11.2.4.2. New State

State remains same.

11.2.5. Transport Parameters Change at MGC

Input parameters:
- New Transport Address.

Vikas, Vivek, Shiv, Prashant

42

INTERNET-DRAFT MEGACO Control Association
 Procedures and State Machine August 2001

11.2.5.1. Steps

- 1) The existing calls are not affected.
- 2) Send Service Change Request to the MG Method as Handoff and MGCIIDToTry set to the new transport parameters.

11.2.5.2. New State

SWIP (SWITCHOVER IN PROGRESS)

11.2.6. Peer Failure Detection at MG

Input parameters: None

11.2.6.1. Steps

- 1) The existing calls are not affected assuming that the standby MG may come up and take over the control of the specified association.
- 2) Start waiting for a new service change command from the standby MG with method as DISCONNECTED and reason as COLD Boot or Warm Boot.

11.2.6.2. New State

SWIP (SWITCHOVER_IN_PROGRESS)

11.2.7. Handoff at Active MGC

Input parameters:
- Service Change MGCIIDToTry.

11.2.7.1. Steps

- 1) Send Service Change Request to the MG Method as Handoff and MGCIIDToTry set to the new MGC.

11.2.7.2. New State

SIP (SHUTDOWN_IN_PROGRESS)

Vikas, Vivek, Shiv, Prashant

43

11.2.8. Restart From MGC

Input parameters:

- Service Change Address.
- Service Change Reason.

11.2.8.1. Steps

- 1) Depending on the service change reason field (Cold Boot or Warm Boot or Service Restored), call contexts would be cleared at MGC as well as at MG.
- 2) Send Service Change Request to the MG with method as RESTART and the other relevant parameters.

11.2.8.2. New State

RIP (RESTART_IN_PROGRESS)

11.2.9. Forced shutdown At MGC

Input parameters: None

11.2.9.1. Steps

- 1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.
- 2) Send Service Change Request to the MG with method as FORCED.

11.2.9.2. New State

INACTIVE_

11.3. SWIP (SWITCHOVER_IN_PROGRESS)

In this state:

- Either the active MGC is waiting for a service change command from the standby MG in case of MG Failover that was received earlier.

- Or the handed-off MGC is waiting for a service change command from the active or the standby MG in case control association was re-directed by the active MGC.

11.3.1. Forced Shutdown at MG

Input parameters: None

11.3.1.1. Steps

- 1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.
- 2) After this, MGC shall wait for the next registration request from the MG going down.

11.3.1.2. New State

RIP (RESTART_IN_PROGRESS)

11.3.2. Graceful shutdown request from MG

11.3.2.1. Steps

- 1) Start the delay timer for value specified in Service change delay.
- 2) Till the expiry of the service change delay, the state of MG control association becomes ASSOCIATION IN SERVICE (AIS).
- 3) Delete all the call contexts abruptly after the completion of the graceful period.
- 4) If the NULL delay was specified, the control association must last for the duration of the time until all the active call contexts are cleared from MGC.

11.3.2.2. New State

ASSOCIATION_IN_SERVICE

11.3.3. Failover at active MG

11.3.3.1. Steps

1) Do nothing.

11.3.3.2. New State

State remains same.

11.3.4. Redundant Takeover at standby MG

11.3.4.1. Steps

2) Depending on the service change reason field (Cold Boot or Warm Boot or Service Restored), call contexts would be cleared at MGC.

3) MGC may do an audit.

11.3.4.2. New State

ASSOCIATION_IN_SERVICE

11.3.5. Forced Shutdown at MGC

11.3.5.1. Steps

1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.

2) Buffer the Forced shutdown request until the MG sends a service change request to re-establish the control association.

3) Once the association is re-established, send the service change command with FORCED method to the same MG so that MG could clear the call contexts at its end.

11.3.5.2. New State

INACTIVE

11.3.6. Restart From MGC

11.3.6.1. Steps

1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.

2) Buffer the Forced shutdown request until the MG sends a service change request to re-establish the control

association.

- 3) Once the association is re-established, send the service change command with FORCED method to the same MG so that MG could clear the call contexts at its end.

11.3.6.2. New State

RIP (RESTART_IN_PROGRESS)

11.3.7. Handoff at Active MGC

11.3.7.1. Steps

- 1) Buffer the MGCIIDToTry parameter until the MG sends a service change request to re-establish the control association.
- 2) Once the association is re-established, send the reply to the MG with the MGCIIDToTry field set to the Handed off MGC except the case that the MG is forcefully going down.

11.3.7.2. New State

SIP (SHUTDOWN_IN_PROGRESS).

11.3.8. Re-registration request from active or standby MG

Input parameters:

- Service Change Version.

11.3.8.1. Steps:

- 1) Examine the service change version of the received message, if present.

- 2) If the MGC is unable to comply with the suggested version then send a Service Change Response to the MG with error 0406 Version not supported. State remains same.
- 3) If the MGC supports the suggested or lower version, send a Service Change Response to the MG the negotiated Service Change Version. The state would become ASSOCIATION_IN_SERVICE.

- 4) Depending on the service change reason field (Cold Boot or Warm Boot or Service Restored), call contexts would be cleared at MGC. MGC should do an audit here as per the protocol.

11.4. SIP (SHUTDOWN_IN_PROGRESS)

11.4.1. Forced Shutdown at MG

11.4.1.1. Steps

- 1) All the call contexts would be cleared at MGC without sending SUBTRACT commands to MG.

11.4.1.2. New State

INACTIVE

11.4.2. Graceful Shutdown at MG

11.4.2.1. Steps

- 1) The MGC going down may convey this information to the Handed-off MGC, outside the scope of the protocol.
- 2) Send the reply to the MG with the MGCIdToTry field set to the Handed-off MGC.

11.4.2.2. New State

State remains same.
