**Camellia Encryption for Kerberos 5
draft-hudson-camellia-cts-00**

Abstract

This document specifies two encryption types and two corresponding checksum types for the Kerberos cryptosystem suite. The new types use the Camellia block cipher in CBC-mode with ciphertext stealing and the CMAC algorithm for integrity protection.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79. Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>. Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress." This Internet-Draft will expire on May 23, 2011.

1. Introduction

The Camellia block cipher, described in [\[RFC3713\] \(Matsui, M., Nakajima, J., and S. Moriai, "A Description of the Camellia Encryption Algorithm," April 2004.\)](#), has a 128-bit block size and a 128-bit, 192-bit, or 256-bit key size, similar to AES. This document specifies Kerberos encryption and checksum types for Camellia using 128-bit or 256-bit keys. The new types conform to the framework specified in [\[RFC3961\] \(Raeburn, K., "Encryption and Checksum Specifications for Kerberos 5," February 2005.\)](#), but do not use the simplified profile. Like the simplified profile, the new types use key derivation to produce keys for encryption, integrity protection, and checksum operations. Instead of the [\[RFC3961\] \(Raeburn, K., "Encryption and Checksum Specifications for Kerberos 5," February 2005.\)](#) section 5.1 key derivation function, the new types use a key derivation function from the family specified in [\[SP800-108\] \(Chen, L., "Recommendation for Key Derivation Using Pseudorandom Functions," October 2009.\)](#).

The new types use the CMAC algorithm for integrity protection and checksum operations. As a consequence, they do not rely on a hash algorithm except when generating keys from strings.

Like the AES encryption types [\[RFC3962\] \(Raeburn, K., "Advanced Encryption Standard \(AES\) Encryption for Kerberos 5," February 2005.\)](#), the new encryption types use CBC mode with ciphertext stealing to avoid the need for padding. They also use the same PBKDF2 algorithm for key generation from strings, with a modification to the salt string to ensure that different keys are generated for Camellia and AES encryption types.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [\[RFC2119\] \(Bradner, S., "Key words for use in RFCs to Indicate Requirement Levels," March 1997.\)](#).

2. Protocol Key Representation

The Camellia key space is dense, so we use random octet strings directly as keys. The first bit of the Camellia bit string is the high bit of the first byte of the random octet string.

3. Key Generation from Strings

We use a variation on the key generation algorithm specified in [\[RFC3962\] \(Raeburn, K., "Advanced Encryption Standard \(AES\) Encryption for Kerberos 5," February 2005.\)](#) section 4.

First, to ensure that different long-term keys are used with Camellia and AES, we prepend the enctype name to the salt string, separated by a

null byte. The enctype name is "camellia128-cts-cmac" or "camellia256-cts-cmac" (without the quotes).

Second, the final key derivation step uses the algorithm described in [Section 4 \(Key Derivation\)](#) instead of the key derivation algorithm used by the simplified profile.

Third, if no string-to-key parameters are specified, the default number of iterations is raised to 32768.

```
saltp = enctype-name | 0x00 | salt
tkey = random2key(PBKDF2-HMAC-SHA1(passphrase, saltp,
                                iter_count, keylength))
key = KDF-FEEDBACK-CMAC(tkey, "kerberos")
```

4. Key Derivation

We use a key derivation function from the family specified in [\[SP800-108\] \(Chen, L., "Recommendation for Key Derivation Using Pseudorandom Functions," October 2009.\)](#) section 5.2, "KDF in Feedback Mode". The PRF parameter of the key derivation function is CMAC with Camellia-128 or Camellia-256 as the underlying block cipher; this PRF has an output size of 128 bits. A block counter is used with a length of 4 bytes, represented in big-endian order. The length of the output key in bits (denoted as k) is also represented as a four-byte string in big-endian order. The label input to the KDF is the usage constant supplied to the key derivation function, and the context is unused.

```
n = ceiling(k / 128)
K0 = zeros
Ki = CMAC(key, K(i-1) | i | constant | 0x00 | k)
DR(key, constant) = k-truncate(K1 | K2 | ... | Kn)
KDF-FEEDBACK-CMAC(key, constant) = random-to-key(DR(key, constant))
```

The constants used for key derivation are the same as those used in the simplified profile.

5. CMAC Checksum Algorithm

For integrity protection and checksums, we use the CMAC function defined in [\[SP800-38B\] \(Dworkin, M., "Recommendation for Block Cipher Modes of Operation: The CMAC Mode for Authentication," October 2009.\)](#), with Camellia-128 or Camellia-256 as the underlying block cipher.

6. Kerberos Algorithm Protocol Parameters

The following parameters apply to the encryption types `camellia128-cts-cmac`, which uses a 128-bit protocol key, and `camellia256-cts-cmac`, which uses a 256-bit protocol key.

Protocol key format: as defined in [Section 2 \(Protocol Key Representation\)](#).

Specific key structure: three protocol format keys: { `Kc`, `Ke`, `Ki` }.

Required checksum mechanism: as defined in [Section 7 \(Checksum Parameters\)](#).

Key generation seed length: the key size (128 or 256 bits).

String-to-key function: as defined in [Section 3 \(Key Generation from Strings\)](#).

Default string-to-key parameters: `00 00 80 00`.

Random-to-key function: identity function.

Key-derivation function: as indicated below, with usage represented as four octets in big-endian order.

```
Kc = KDF-FEEDBACK-CMAC(base-key, usage | 0x99)
Ke = KDF-FEEDBACK-CMAC(base-key, usage | 0xAA)
Ki = KDF-FEEDBACK-CMAC(base-key, usage | 0x55)
```

Initial cipher state: all bits zero.

Encryption function: as follows, where `E()` is Camellia encryption in CBC-CTS mode, with the next-to-last block used as the CBC-style ivec, or the last block if there is only one.

```
conf = Random string of 128 bits
(C, newstate.ivec) = E(Ke, conf | plaintext, oldstate.ivec)
M = CMAC(Ki, conf | plaintext)
ciphertext = C | M
```

Decryption function: as follows, where `D()` is Camellia decryption in CBC-CTS mode, with the ivec treated as in `E()`.

```
(C, M) = ciphertext
(P, newIV) = D(Ke, C, oldstate.ivec)
if (M != CMAC(Ki, P)) report error
newstate.ivec = newIV
```

Pseudo-random function: as follows.

```
Kp = KDF-FEEDBACK-CMAC(protocol-key, "prf")
PRF = CMAC(Kp, octet-string)
```

7. Checksum Parameters

The following parameters apply to the checksum types `cmac-camellia128` and `cmac-camellia256`, which are the associated checksum for `camellia128-cts-cmac` and `camellia256-cts-cmac` respectively.

Associated cryptosystem: Camellia-128 or Camellia-256 as appropriate for the checksum type.

`get_mic`: CMAC(Kc, message).

`verify_mic`: `get_mic` and compare.

8. Assigned Numbers

Encryption types

Type name	etype	value	key size
<code>camellia128-cts-cmac</code>	TBD		128
<code>camellia256-cts-cmac</code>	TBD		256

Checksum types

Type name	sumtype	value	length
<code>cmac-camellia128</code>	TBD		128
<code>cmac-camellia256</code>	TBD		128

9. Security Considerations

[\[CRYPTOENG\] \(Schneier, B., "Cryptography Engineering," March 2010.\)](#)

chapter 4 discusses weaknesses of the CBC cipher mode. An attacker who can observe enough messages generated with the same key to encounter a collision in ciphertext blocks could recover the XOR of the plaintexts of the previous blocks. Observing such a collision becomes likely as the number of blocks observed approaches 2^{64} . This consideration applies to all previously standardized Kerberos encryption types and all uses of CBC encryption with 128-bit block ciphers in other protocols. Kerberos deployments can mitigate this concern by rolling over keys often enough to make observing 2^{64} messages unlikely. Because the new checksum types are deterministic, an attacker could pre-compute checksums for a known plain-text message in 2^{64} randomly chosen protocol keys. The attacker could then observe checksums legitimately computed in different keys until a collision with one of the pre-computed keys is observed; this becomes likely after the number of observed checksums approaches 2^{64} . Observing such a collision allows the attacker to recover the protocol key. This consideration

applies to most previously standardized Kerberos checksum types and most uses of 128-bit checksums in other protocols.

The Camellia cipher has not received as much scrutiny as AES. Kerberos deployments should not migrate to the Camellia encryption types simply because they are newer, but should use them only if business needs require the use of Camellia, or if a serious flaw is discovered in AES which does not apply to Camellia.

The security considerations described in [\[RFC3962\] \(Raeburn, K., "Advanced Encryption Standard \(AES\) Encryption for Kerberos 5," February 2005.\)](#) section 8 regarding the string-to-key algorithm also apply to the Camellia encryption types.

256-bit Camellia key:
32 16 4C 5B 43 4D 1D 15 38 E4 CF D9 BE 80 40 FE
8C 4A C7 AC C4 B9 3D 33 14 D2 13 36 68 14 7A 05
Key usage: 10
Checksum:
3F A0 B4 23 55 E5 2B 18 91 87 29 4A A2 52 AB 64
```
