Improving the Robustness of Stateless Address Autoconfiguration (SLAAC) to Flash Renumbering Events

Abstract

In renumbering scenarios where an IPv6 prefix suddenly becomes invalid, hosts on the local network will continue using stale prefixes for an unacceptably long period of time, thus resulting in connectivity problems. This document improves the reaction of IPv6 Stateless Address Autoconfiguration to such renumbering scenarios. It formally updates RFC 4191, RFC 4861, RFC 4862, and RFC 8106.

1. **Introduction**

   In scenarios where network configuration information becomes invalid
   without any explicit signaling of that condition, hosts on the local
   network will continue using stale information for an unacceptably
   long period of time, thus resulting in connectivity problems. This
   problem has been discussed in detail in [RFC8978].

   This document updates the Neighbor Discovery specification
   [RFC4861], the Stateless Address Autoconfiguration (SLAAC)
   specification [RFC4862], and other associated specifications
   ([RFC4191] and [RFC8106]), such that hosts can more gracefully deal
   with the so-called flash renumbering events, thus improving the
   robustness of SLAAC.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. SLAAC reaction to Flash-renumbering Events

In some scenarios, the local router triggering the network renumbering event may try to deprecate the stale information (by explicitly signaling the network about the renumbering event), whereas in other scenarios the renumbering event may happen inadvertently, without the router explicitly signaling the scenario to local hosts. The following subsections analyze specific considerations for each of these scenarios.

3.1. Renumbering without Explicit Signaling

In the absence of explicit signalling from SLAAC routers (such as sending Prefix Information Options (PIOs) with small lifetimes to deprecate stale prefixes), stale prefixes will remain preferred and valid according to the Preferred Lifetime and Valid Lifetime parameters (respectively) of the last received PIO. [RFC4861] specifies the following default values for PIOs:

  *Preferred Lifetime (AdvPreferredLifetime): 604800 seconds (7
   days)

  *Valid Lifetime (AdvValidLifetime): 2592000 seconds (30 days)

This means that, in the absence of explicit signaling by a SLAAC router to deprecate a prefix, it will take a host 7 days (one week) to deprecate the corresponding addresses, and 30 days (one month) to eventually remove any addresses configured for the stale prefix. Clearly, employing such long default values is unacceptable for most deployment scenarios that may experience flash-renumbering events.

NOTE:
   [RFC8978] provides an operational recommendation for Customer
   Edge (CE) routers to override the standard default Preferred
   Lifetime (AdvPreferredLifetime) and Valid Lifetime
   (AdvValidLifetime) to 2700 seconds (45 minutes) and 5400 seconds
   (90 minutes), respectively, thus improving the state of affairs
   for CE router scenarios.

Similarly, other Neighbor Discovery options employ unnecessarily long default lifetimes that are unacceptable for most deployment scenarios that may experience flash-renumbering events.

Use of more appropriate timers in Router Advertisement messages can help limit the amount of time that hosts will maintain stale configuration information. Thus, Section 4.1 formally specifies the use of more appropriate (i.e., shorter) default lifetimes for Neighbor Discovery options.

3.2. Renumbering with Explicit Signaling

In scenarios where a local router is aware about the renumbering event, it may try to phase out the stale network configuration information. In these scenarios, there are two aspects to be considered:

   *The amount of time during which the router should continue trying to deprecate the stale network configuration information.

   *The ability of SLAAC hosts to phase out stale configuration.

Since the network could be become partitioned at any arbitrary time and for an arbitrarily long period of time, routers need to contemplate the possible scenario where hosts receive an RA message, and the network subsequently becomes partitioned. This means that in order to reliably deprecate stale information, a router would should try to deprecate such information for a period of time equal to the associated Neighbor Discovery option lifetime used when the information was advertised.

NOTE:
   For example, it should try to deprecate a prefix (via a PIO) for a period of time equal to the "Preferred Lifetime" used when advertising the prefix, and try to invalidate the prefix for a period of time equal to the "Valid Lifetime" (see Section 12 of [RFC4861]) used when advertising the prefix.

   Once the number of seconds in the original "Preferred Lifetime" have elapsed, all hosts will have deprecated the corresponding addresses, while once the number of seconds in the "Valid Lifetime" have elapsed, the corresponding addresses will be invalidated and removed.

Thus, use of more appropriate default lifetimes for Neighor Discovery options, as specified in Section 4.1, would reduce the amount of time stale options would need to be advertised by a router to ensure that the associated information is phased out.

In the case of Prefix Information Options (PIOs), in scenarios where a router has positive knowledge that a prefix has become invalid (and thus could signal this condition to local hosts), the current specifications will prevent SLAAC hosts from fully recovering from such stale information: Item "e)" of Section 5.5.3 of [RFC4862]

specifies that an RA may never reduce the "RemainingLifetime" to
less than two hours. Additionally, if the RemainingLifetime of an
address is smaller than 2 hours, then a Valid Lifetime smaller than
2 hours will be ignored. The inability to invalidate a stale prefix
may prevent communications with the new "owners" of a prefix, and
thus is highly undesirable. However, the Preferred Lifetime of an
address *may* be reduced to any value to avoid the use of a stale
prefix for new communications.

Section 4.2 formally updates [RFC4862] to remove this restriction,
such that hosts may react to the advertised "Valid Lifetime" even if
it is smaller than 2 hours. Section 4.3 recommends that routers
disseminate network configuration information when a network
interface is initialized, such that new configuration information
propagates in a timelier manner.

4. **Improvements to Stateless Address Autoconfiguration (SLAAC)**

The following subsections update [RFC4861] and [RFC4862], such that
the problem discussed in this document is mitigated. The updates in
the following subsections are mostly orthogonal, and mitigate
different aspects of SLAAC that prevent a timely reaction to flash
renumbering events:

  *Reduce the default Valid Lifetime and Preferred Lifetime of PIOs
   (Section 4.1):

   This helps limit the amount of time a host may employ stale
   information, and also limits the amount of time a router needs to
   try to deprecate stale information.

  *Honor PIOs with small Valid Lifetimes (Section 4.2):

   This allows routers to invalidate stale prefixes, since otherwise
   [RFC4861] would prevent hosts from honoring PIOs with a Valid
   Lifetime smaller than two hours.

  *Recommend routers to retransmit configuration information upon
   interface initialization/reinitialization (Section 4.3):

   This helps spread the new information in a timelier manner.

  *Recommend routers to always send all options (i.e. the complete
   configuration information) in RA messages, and in the smallest
   possible number of packets (Section 4.4):

   This helps propagate the same information to all hosts.

4.1. More Appropriate Neighbor Discovery Option Lifetimes

This document defines the following variables to be employed for the
default lifetimes of Neighbor Discovery options:

  *ND_DEFAULT_PREFERRED_LIFETIME: max(AdvDefaultLifetime, 3 *
   MaxRtrAdvInterval)

  *ND_DEFAULT_VALID_LIFETIME: 2 * ND_DEFAULT_PREFERRED_LIFETIME

where:

AdvDefaultLifetime:
   Router configuration variable specified in [RFC4861], which
   specifies the value to be placed in the Router Lifetime field of
   Router Advertisements sent from the interface, in seconds.

MaxRtrAdvInterval:
   Router configuration variable specified in [RFC4861], which
   specifies the maximum time allowed between sending unsolicited
   multicast Router Advertisements from the interface, in seconds.

max():
   A function that computes the maximum of its arguments.

NOTE:
   The expression above computes of maximum among AdvDefaultLifetime
   and "3 * MaxRtrAdvInterval" (the default value of
   AdvDefaultLifetime, as per [RFC4861]) to accommodate the case
   where an operator might simply want to disable one local router
   for maintenance, while still having the router advertise SLAAC
   configuration information.

   [RFC4861] specifies the default value of MaxRtrAdvInterval as 600
   seconds, and the default value of AdvDefaultLifetime as 3 *
   MaxRtrAdvInterval. Therefore, when employing default values for
   MaxRtrAdvInterval and AdvDefaultLifetime, the default values of
   ND_DEFAULT_PREFERRED_LIFETIME and ND_DEFAULT_VALID_LIFETIME
   become 1800 seconds (30 minutes) and 3600 seconds (1 one hour),
   respectively. We note that when implementing BCP202 [RFC7772],
   AdvDefaultLifetime will typically be in the range of 45-90
   minutes, and therefore the value of ND_DEFAULT_PREFERRED_LIFETIME
   will be in the range 45-90 minutes, while the value of
   ND_DEFAULT_VALID_LIFETIME will be in the range of 90-180 minutes.

This document formally updates [RFC4861] to modify the default
values of the Preferred Lifetime and the Valid Lifetime of PIOs as
follows:

  *AdvPreferredLifetime: ND_DEFAULT_PREFERRED_LIFETIME

*AdvValidLifetime: ND_DEFAULT_VALID_LIFETIME

This document formally updates [RFC4191] to specify the default
Route Lifetime of Route Information Options (RIOs) as follows:

   *Route Lifetime: Default: ND_DEFAULT_PREFERRED_LIFETIME

This document formally updates [RFC8106] to modify the default
Lifetime of Recursive DNS Server Options as:

   *Lifetime: Default: ND_DEFAULT_PREFERRED_LIFETIME

Additionally, this document formally updates [RFC8106] to modify the
default Lifetime of DNS Search List Options as:

   *Lifetime: Default: ND_DEFAULT_PREFERRED_LIFETIME

4.2. Honor Small PIO Valid Lifetimes

The entire item "e)" (pp. 19-20) from Section 5.5.3 of [RFC4862] is
replaced with the following text:

   e) If the advertised prefix is equal to the prefix of an address
   configured by stateless autoconfiguration in the list, the valid
   lifetime and the preferred lifetime of the address should be
   updated by processing the Valid Lifetime and the Preferred
   Lifetime (respectively) in the received advertisement.

RATIONALE: This change allows hosts to react to the signal provided
            by a router that has positive knowledge that a prefix has
            become invalid.

      *The behavior described in [RFC4862] had been incorporated
       during the revision of the original IPv6 Stateless Address
       Autoconfiguration specification ([RFC1971]). At the time,
       the IPNG working group decided to mitigate the attack
       vector represented by Prefix Information Options with very
       short lifetimes, on the premise that these packets
       represented a bigger risk than other ND-based attack
       vectors [IPNG-minutes].

       While reconsidering the trade-offs represented by such
       decision, we conclude that the drawbacks of the
       aforementioned mitigation outweigh the possible benefits.

       In scenarios where RA-based attacks are of concern, proper
       mitigations such as RA-Guard [RFC6105] [RFC7113] or SEND
       [RFC3971] should be implemented.

4.3. Interface Initialization

When an interface is initialized, it is paramount that network
configuration information is propagated on the corresponding network
(particularly in scenarios where an interface has been re-
initialized, and the conveyed information has changed). Thus, this
document replaces the following text from Section 6.2.4 of
[RFC4861]:

> In such cases, the router MAY transmit up to
> MAX_INITIAL_RTR_ADVERTISEMENTS unsolicited advertisements, using
> the same rules as when an interface becomes an advertising
> interface.

with:

> In such cases, the router SHOULD transmit
> MAX_INITIAL_RTR_ADVERTISEMENTS unsolicited advertisements, using
> the same rules as when an interface becomes an advertising
> interface.

RATIONALE: Use of stale information can lead to interoperability
problems. Therefore, it is important that new configuration
information propagates in a timelier manner to all hosts.

NOTE:
   [RFC9096] specifies recommendations for CPE routers to signal any
   stale network configuration information.

4.4. Conveying Information in Router Advertisement (RA) Messages

Intentionally omitting information in Router Advertisements may
prevent the propagation of such information, and may represent a
challenge for hosts that need to infer whether they have received a
complete set of SLAAC configuration information. As a result, this
section recommends that, to the extent that is possible, RA messages
contain a complete set of SLAAC information.

This document replaces the following text from Section 6.2.3 of
[RFC4861]:

> A router MAY choose not to include some or all options when
> sending unsolicited Router Advertisements. For example, if prefix
> lifetimes are much longer than AdvDefaultLifetime, including them
> every few advertisements may be sufficient. However, when
> responding to a Router Solicitation or while sending the first
> few initial unsolicited advertisements, a router SHOULD include

all options so that all information (e.g., prefixes) is
propagated quickly during system initialization.

If including all options causes the size of an advertisement to
exceed the link MTU, multiple advertisements can be sent, each
containing a subset of the options.

with:

When sending Router Advertisements, a router SHOULD include all
options.

If including all options would cause the size of an advertisement
to exceed the link MTU, multiple advertisements can be sent, each
containing a subset of the options. In all cases, routers SHOULD
convey all information using the smallest possible number of
packets, and SHOULD convey options of the same type in the same
packet to the extent possible.

RATIONALE: Sending information in the smallest possible number of
packets was somewhat already implied by the original text
in [RFC4861]. Including all options when sending RAs leads
to simpler code (as opposed to dealing with special cases
where specific information is intentionally omitted), and
also helps hosts infer when they have received a complete
set of SLAAC configuration information. Note that while
[RFC4861] allowed some RAs to omit some options, to the
best of the authors' knowledge, all SLAAC router
implementations always send all options in the smallest
possible number of packets. Therefore, this section simply
aligns the protocol specifications with existing
implementation practice.

5. IANA Considerations

This document has no actions for IANA.

6. Implementation Status

[NOTE: This section is to be removed by the RFC-Editor before this
document is published as an RFC.]

This section summarizes the implementation status of the updates
proposed in this document. In some cases, they correspond to
variants of the mitigations proposed in this document (e.g., use of
reduced default lifetimes for PIOs, albeit using different values
than those recommended in this document). In such cases, we believe
these implementations signal the intent to deal with the problems
described in [RFC8978] while lacking any guidance on the best
possible approach to do it.

6.1. More Appropriate Lifetime Values

6.1.1. Router Configuration Variables

6.1.1.1. rad(8)

We have produced a patch for OpenBSD's rad(8) [rad] that employs the default lifetimes recommended in this document, albeit it has not yet been committed to the tree. The patch is available at: <https://www.gont.com.ar/code/fgont-patch-rad-pio-lifetimes.txt>.

6.1.1.2. radvd(8)

The radvd(8) daemon [radvd], normally employed by Linux-based router implementations, currently employs different default lifetimes than those recommended in [RFC4861]. radvd(8) employs the following default values [radvd.conf]:

   *Preferred Lifetime: 14400 seconds (4 hours)

   *Valid Lifetime: 86400 seconds (1 day)

This is not following the specific recommendation in this document, but is already a deviation from the current standards.

6.2. Honor Small PIO Valid Lifetimes

6.2.1. Linux Kernel

A Linux kernel implementation of this document has been committed to the net-next tree. The implementation was produced in April 2020 by Fernando Gont <fgont@si6networks.com>. The corresponding patch can be found at: <https://patchwork.ozlabs.org/project/netdev/patch/20200419122457.GA971@archlinux-current.localdomain/>

6.2.2. NetworkManager

NetworkManager [NetworkManager] processes RA messages with a Valid Lifetime smaller than two hours as recommended in this document.

6.3. Conveying Information in Router Advertisement (RA) Messages

We know of no implementation that splits network configuration information into multiple RA messages.

6.4. Recovery from Stale Configuration Information without Explicit Signaling

6.4.1. dhcpcd(8)

The dhcpcd(8) daemon [dhcpcd], a user-space SLAAC implementation employed by some Linux-based and BSD-derived operating systems, will set the Preferred Lifetime of addresses corresponding to a given prefix to 0 when a single RA from the router that previously advertised the prefix fails to advertise the corresponding prefix. However, it does not affect the corresponding Valid Lifetime. Therefore, it can be considered a partial implementation of this feature.

6.5. Other mitigations implemented in products

[FRITZ] is a Customer Edge Router that tries to deprecate stale prefixes by advertising stale prefixes with a Preferred Lifetime of 0, and a Valid Lifetime of 2 hours (or less). There are two things to note with respect to this implementation:

  *Rather than recording prefixes on stable storage (as recommended in [RFC9096]), this implementation checks the source address of IPv6 packets, and assumes that usage of any address that does not correspond to a prefix currently-advertised by the Customer Edge Router is the result of stale network configuration information. Hence, upon receipt of a packet that employs a source address that does not correspond to a currently-advertised prefix, this implementation will start advertising the corresponding prefix with small lifetimes, with the intent of deprecating it.

  *Possibly as a result of item "e)" (pp. 19-20) from Section 5.5.3 of [RFC4862] (discussed in Section 4.2 of this document), upon first occurrence of a stale prefix, this implementation will employ a decreasing Valid Lifetime, starting from 2 hours (7200 seconds), as opposed to a Valid Lifetime of 0.

7. Security Considerations

The protocol update in Section 4.2 could allow an on-link attacker to perform a Denial of Service attack against local hosts, by sending a forged RA with a PIO with a Valid Lifetime of 0. Upon receipt of that packet, local hosts would invalidate the corresponding prefix, and therefore remove any addresses configured for that prefix, possibly terminating e.g. associated TCP connections. However, an attacker may achieve similar effects via a number other Neighbor Discovery (ND) attack vectors, such as directing traffic to a non-existing node until ongoing TCP connections time out, or performing a ND-based man-in-the-middle (MITM) attack and subsequently forging TCP RST segments to cause on-

going TCP connections to be reset. Thus, for all practical purposes, this attack vector does not really represent any greater risk than other ND attack vectors. As noted in Section 4.2 , in scenarios where RA-based attacks are of concern, proper mitigations such as RA-Guard [RFC6105] [RFC7113] or SEND [RFC3971] should be implemented.
