Abstract

This document extends the Application-Layer Traffic Optimization (ALTO) Protocol [RFC7285] by generalizing the concept of "endpoint properties" to other entity domains, and by presenting those properties as maps, similar to the network and cost maps in ALTO.

1. Introduction

The ALTO protocol [RFC7285] introduced the concept of "properties" attached to "endpoint addresses", and defined the Endpoint Property Service (EPS) to allow clients to retrieve those properties. While useful, the EPS, as defined in RFC7285, has at least two limitations.
First, it only allows properties to be associated with a particular domain of entities, namely individual IP addresses. It is reasonable to think that collections of endpoints, as defined by CIDRs ([RFC4632]) or PIDs, may also have properties. Furthermore, a recent proposal ([I-D.ietf-alto-path-vector]) has suggested new classes of entities (ANE) with properties. The EPS cannot be extended to new entity domains. Instead, new services, with new request and response messages, would have to be defined for each new entity domain.

Second, the EPS is only defined as a POST-mode service. Clients must request the properties for an explicit set of addresses. By contrast, [RFC7285] defines a GET-mode Cost Map resource which returns all available costs, so a client can get a full set of costs once, and then processes costs lookup without querying the ALTO server. RFC7285 does not define an equivalent service for endpoint properties. And it is unlikely a property will be defined for every possible address. It is very likely that properties will only be defined for a subset of addresses, and that subset would be small enough to enumerate. This is particularly true if blocks of addresses with a common prefix (e.g., a CIDR) have the same value for a property. Furthermore, entities in other domains may very well be enumerable.

This document proposes a new approach to retrieve ALTO properties. Specifically, it defines two new resource types, namely Property Maps (see Section 4) and Filtered Property Maps (see Section 5). The former are GET-mode resources which return the property values for all entities in a domain, and are analogous to the ALTO's Network Maps and Cost Maps. The latter are POST-mode resources which return the values for a set of properties and entities requested by the client, and are analogous to the ALTO's Filtered Network Maps and Filtered Cost Maps.

Entity domains and property names are extensible. New domains can be defined without revising the messages defined in this document, in the same way that new cost metrics and new endpoint properties can be defined without revising the messages defined by the ALTO protocol.

This proposal would subsume the Endpoint Property Service defined in RFC7285, although that service may be retained for legacy clients.
2. Definitions and Concepts

2.1. Entity

An entity is an object with a (possibly empty) set of properties. Every entity is in a domain, such as the IPv4 and IPv6 domains, and has a unique address.

2.2. Domain

A domain is a family of entities. Two examples are the Internet address and PID domain (see Section 3.1 and Section 3.2) that this document will define. An additional example is the proposed domain of Abstract Network Elements associated with topology and routing, as suggested by [I-D.ietf-alto-path-vector].

2.3. Domain Name

Each domain has a unique name. A domain name MUST be no more than 32 characters, and MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), hyphen ('-', U+002D), and low line ('_', U+005F). For example, the names "ipv4" and "ipv6" identify objects in the Internet address domain (Section 3.1).

The type DomainName is used in this document to denote a JSON string with a domain name in this format.

Domain names MUST be registered with the IANA, and the format of the entity addresses in that domain, as well as any hierarchical or inheritance rules for those entities, MUST be specified at the same time.

2.4. Entity Address

Each entity has a unique address of the format:

    domain-name : domain-specific-entity-address
Examples from the IP domain include individual addresses such as "ipv4:192.0.2.14" and "ipv6:2001:db8::12", as well as address blocks such as "ipv4:192.0.2.0/26" and "ipv6:2001:db8::1/48".

The type EntityAddr is used in this document to denote a JSON string with an entity address in this format.

The format of the second part of an entity address depends on the domain, and MUST be specified when registering a new domain. Addresses MAY be hierarchical, and properties MAY be inherited based on that hierarchy. Again, the rules defining any hierarchy or inheritance MUST be defined when the domain is registered.

Note that entity addresses MAY have different textual representations, for a given domain. For example, the strings "ipv6:2001:db8::1" and "ipv6:2001:db8:0:0:0:0:0:1" refer to the same entity.

2.5. Property Name

The space of property names associated with entities defined by this document is the same as, and is shared with, the endpoint property names defined by [RFC7285]. Thus entity property names are as defined in Section 10.8.2 of that document, and must be registered with the "ALTO Endpoint Property Type Registry" defined in Section 9.3 of that document. The type PropertyName denotes a JSON string with a property name in this format.

This document defines uniform property names specified in a single property name space rather than being scoped by a specific domain, although some properties may only be applicable for particular domains. This design decision is to enforce a design so that similar properties are named similarly. The interpretation of the value of a property, however, may depend on the domain. For example, suppose the "geo-location" property is defined as the coordinates of a point, encoded as (say) "latitude longitude [altitude]." When applied to an entity that represents a specific host computer, such as an Internet address, the property defines the host's location. When applied to an entity that represents a set of computers, such as a CIDR, the property would be the location of the center of that set. If it is
necessary to represent the bounding box of a set of hosts, another property, such as "geo-region", should be defined.

2.6. Hierarchy and Inheritance

Entities in a given domain MAY form hierarchy based on entity address. Each domain MUST define its own hierarchy and inheritance rules when registered. The hierarchy and inheritance rule makes it possible for an entity to inherit a property value from another entity in the same domain. If and only if the property of an entity is undefined, the hierarchy and inheritance rules are applied.

2.7. Relationship with Other ALTO Resources

[RFC7285] recognizes that some properties MAY be specific to another ALTO resource, such as a network map. Accordingly [RFC7285] defines the concept of "resource-specific endpoint properties" (Section 10.8.1), and indicates that dependency by prefixing the property name with the ID of the resource on which it depends. That document defines one resource-specific property, namely the "pid" property, whose value is the name of the PID containing that endpoint in the associated network map.

This document takes a different approach. Instead of defining the dependency by qualifying the property name, this document attaches the dependency to the domains. Thus all properties of a specific domain depend on the same resource, the properties of another domain may depend on another resource. For example, entities in the PID domain depends on a network map, entities in the ANE domain depends on a cost map or a endpoint cost map.

The "uses" field in an IRD entry defines the dependencies of a property map resource, and the "dependent-vtags" field in a property map response defines the dependencies of that map. These fields are defined in Sections 9.1.5 and 11.1 of [RFC7285], respectively.

The "uses" field in an IRD entry MUST NOT include two dependent resources with the same media type. This is similar to how RFC7285 handles dependencies between cost maps and network maps. Recall that cost maps present the costs between PIDs, and PID names depend on a network map. If an ALTO server provides the "routingcost" metric for
the network maps "net1" and "net2", then the server defines two separate cost maps, one for "net1" and the other for "net2".

According to [RFC7285], a legacy ALTO server with two network maps, with resource IDs "net1" and "net2", could offer a single Endpoint Property Service for the two properties "net1.pid" and "net2.pid". An ALTO server which supports the extensions defined in this document, would, instead, offer two different Property Maps for the "pid" property, one depending on "net1", the other on "net2".

3. Entity Domains

This document defines the following entity domains. For the definition of each domain, it includes the following template: domain name, domain-specific addresses, and hierarchy and inheritance semantics.

3.1. Internet Address Domains

The document defines two domains (IPv4 and IPv6) for Internet addresses. Both domains include individual addresses and blocks of addresses.

3.1.1. IPv4 Domain

3.1.1.1. Domain Name

ipv4

3.1.1.2. Domain-Specific Entity Addresses

Individual addresses are strings as specified by the IPv4Addresses rule of Section 3.2.2 of [RFC3986]. Blocks of addresses are prefix-match strings as specified in Section 3.1 of [RFC4632]. For the purpose of defining properties, an individual Internet address and the corresponding full-length prefix are considered aliases for the same entity. Thus "ipv4:192.0.2.0" and "ipv4:192.0.2.0/32" are equivalent.

3.1.2. IPv6 Domain
3.1.2.1. Domain Name

ipv6

3.1.2.2. Domain-Specific Entity Addresses

Individual addresses are strings as specified by Section 4 of [RFC5952]. Blocks of addresses are prefix-match strings as specified in Section 7 of [RFC5952]. For the purpose of defining properties, an individual Internet address and the corresponding 128-bit prefix are considered aliases for the same entity. That is, "ipv6:2001:db8::1" and "ipv6:2001:db8::1/128" are equivalent, and have the same set of properties.

3.1.3. Hierarchy and Inheritance of ipv4/ipv6 Domains

Both domains allow property values to be inherited. Specifically, if a property P is not defined for a specific Internet address I, but P is defined for some block C which prefix-matches I, then the address I inherits the value of P defined for block C. If more than one such block defines a value for P, I inherits the value of P in the block with the longest prefix. It is important to notice that this longest prefix rule will ensure no multiple inheritance, and hence no ambiguity.

Address blocks can also inherit properties: if property P is not defined for a block C, but is defined for some block C' prefix-matches C, and C' has a shorter mask than C, then block C inherits the property from C'. If there are several such blocks C', C inherits from the block with the longest prefix.

As an example, suppose that a server defines the property P for the following entities:

<table>
<thead>
<tr>
<th>Address</th>
<th>Property Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4:192.0.2.0/26</td>
<td>P=v1</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/28</td>
<td>P=v2</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/30</td>
<td>P=v3</td>
</tr>
<tr>
<td>ipv4:192.0.2.0</td>
<td>P=v4</td>
</tr>
</tbody>
</table>

Figure 1: Defined Property Values.

Then the following entities have the indicated values:
Figure 2: Inherited Property Values.

An ALTO Server MAY explicitly indicate a property as not having a value for a particular entity. That is, a server MAY say that property A of entity X is "defined to have no value", instead of "undefined". To indicate "no value", a server MAY perform different behaviours:

- If that entity would inherit a value for that property, then the ALTO server MUST return a "null" value for that property. In this case, the ALTO client MUST recognize a "null" value as "no value" and "do not apply the inheritance rules for this property."

- If the entity would not inherit a value, then the ALTO server MAY return "null" or just omit the property. In this case, the ALTO client cannot infer the value for this property of this entity from the Inheritance rules. So the client MUST interpret this property has "no value".

If the ALTO Server does not define any properties for an entity, then the server MAY omit that entity from the response.

3.1.4. Relationship to Network Maps

An Internet address domain MAY be associated with an ALTO network map resource. Logically, there is a map of Internet address entities to property values for each network map defined by the ALTO server, plus an additional property map for Internet address entities which are not associated with a network map. So, if there is n network maps, the server can provide n+1 maps of Internet address entities to property values. These maps are separate from each other. The prefixes in the property map do not have to correspond to the prefixes defining the network map's PIDs. For example, the property map for a network map MAY assign properties to "ipv4:192.0.2.0/24" even if that prefix is not associated with any PID in the network.
3.2. PID Domain

The PID domain associates property values with the PIDs in a network map. Accordingly, this domain always depends on a network map.

3.2.1. Domain Name

pid

3.2.2. Domain-Specific Entity Addresses

The entity addresses are the PID names of the associated network map.

3.2.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with PIDs.

3.2.4. Relationship To Internet Address Domains

The PID domain and the Internet address domains are completely independent; the properties associated with a PID have no relation to the properties associated with the prefixes or endpoint addresses in that PID. An ALTO server MAY choose to assign some or all properties of a PID to the prefixes in that PID.

For example, suppose "PID1" consists of the prefix "ipv4:192.0.2.0/24", and has the property "P" with value "v1". The Internet address entities "ipv4:192.0.2.0" and "ipv4:192.0.2.0/24", in the IPv4 domain MAY have a value for the property "P", and if they do, it is not necessarily "v1".

3.3. Internet Address Properties vs. PID Properties

Because the Internet address and PID domains are completely separate, the question may arise as to which domain is best for a property. In general, the Internet address domain is RECOMMENDED for properties that are closely related to the Internet address, or are associated with, and inherited through, blocks of addresses.
The PID domain is RECOMMENDED for properties that arise from the definition of the PID, rather than from the Internet address prefixes in that PID.

For example, because Internet addresses are allocated to service providers by blocks of prefixes, an "ISP" property would be best associated with the Internet address domain. On the other hand, a property that explains why a PID was formed, or how it relates the a provider's network, would best be associated with the PID domain.

3.4. ANE Domain

3.4.1. Domain Name

ane

3.4.2. Domain-Specific Entity Addresses

The entity address of ane domain is encoded as a JSON string. The string MUST be no more than 64 characters, and it MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), the hyphen ('-', U+002D), the colon (':', U+003A), the at sign ('@', code point U+0040), the low line ('_', U+005F), or the '.' separator (U+002E). The '.' separator is reserved for future use and MUST NOT be used unless specifically indicated in this document, or an extension document.

3.4.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with ANEs.

4. Property Map Resource

A Property Map returns the properties defined for all entities in one or more domains.

Section 7.4 gives an example of a property map request and its
response.

4.1. Media Type

The media type of an ALTO Property Map resource is "application/alto-propmap+json".

4.2. HTTP Method

An ALTO Property Map resource is requested using the HTTP GET method.

4.3. Accept Input Parameters

None.

4.4. Capabilities

The capabilities are defined by an object of type PropertyMapCapabilities:

    object {
        DomainName domain-types<1..*>;  
        PropertyName prop-types<1..*>;  
    } PropertyMapCapabilities;

where "domain-types" is an array with the domains of the entities in this property map, and "prop-types" is an array with the names of the properties returned for entities in those domains.

4.5. Uses

An array with the resource ID(s) of resource(s) with which the domains in this map are associated. In most cases, this array will have at most one ID, for example, for a network map resource. However, the "uses" field MUST NOT contain two resources of the same resource type. For example, if a property map depends on network map resource, the "uses" field MUST include exactly one network map resource.

4.6. Response
If the domains in this property map depend on other resources, the "dependent-vtags" field in the "meta" field of the response MUST be an array that includes the version tags of those resources. The data component of a Property Map response is named "property-map", which is a JSON object of type PropertyMapData, where:

```json
object {
    PropertyMapData property-map;
} InfoResourceProperties : ResponseEntityBase;
```

```json
object-map {
    EntityAddr -> EntityProps;
} PropertyMapData;
```

```json
object {
    PropertyName -> JSONValue;
} EntityProps;
```

The ResponseEntityBase type is defined in Section 8.4 of [RFC7285].

Specifically, a PropertyMapData object has one member for each entity in the Property Map. The entity's properties are encoded in the corresponding EntityProps object. EntityProps encodes one name/value pair for each property, where the property names are encoded as strings of type PropertyName. A protocol implementation SHOULD assume that the property value is either a JSONString or a JSON "null" value, and fail to parse if it is not, unless the implementation is using an extension to this document that indicates when and how property values of other data types are signaled.

For each entity in the Property Map, the ALTO Server returns the value defined for each of the properties specified in this resource's "capabilities" list. For efficiency, the ALTO Server SHOULD omit property values that are inherited rather than explicitly defined; if a client needs inherited values, the client SHOULD use the domain's inheritance rules to deduce those values.

5. Filtered Property Map Resource

A Filtered Property Map returns the values of a set of properties for
a set of entities selected by the client.

Section 7.5, Section 7.6 and Section 7.7 give examples of filtered property map requests and responses.

5.1. Media Type

The media type of an ALTO Property Map resource is "application/alto-propmap+json".

5.2. HTTP Method

An ALTO Filtered Property Map resource is requested using the HTTP POST method.

5.3. Accept Input Parameters

The input parameters for a Filtered Property Map request are supplied in the entity body of the POST request. This document specifies the input parameters with a data format indicated by the media type "application/alto-propmapparams+json", which is a JSON object of type ReqFilteredPropertyMap:

```
object {
    EntityAddr entities<1..*>;
    PropertyName properties<1..*>;
} ReqFilteredPropertyMap;
```

entities: List of entity addresses for which the specified properties are to be returned. The ALTO server MUST interpret entries appearing multiple times as if they appeared only once. The domain of each entity MUST be included in the list of domains in this resource's "capabilities" field (Section 5.4).

properties: List of properties to be returned for each entity. Each specified property MUST be included in the list of properties in this resource's "capabilities" field (Section 5.4). The ALTO server MUST interpret entries appearing multiple times as if they appeared only once.
Note that the "entities" and "properties" fields MUST have at least one entry each.

5.4. Capabilities

The capabilities are defined by an object of type PropertyMapCapabilities, as defined in Section 4.4.

5.5. Uses

An array with the resource ID(s) of resource(s) with which the domains in this map are associated. In most cases, this array will have at most one ID, and it will be for a network map resource.

5.6. Response

The response is the same as for the property map (Section 4.6), except that it only includes the entities and properties requested by the client.

Also, the Filtered Property Map response MUST include all inherited property values for the specified entities (unlike the Full Property Map, the Filtered Property Map response does not include enough information for the client to calculate the inherited values).

6. Impact on Legacy ALTO Servers and ALTO Clients

6.1. Impact on Endpoint Property Service

The Property Maps defined in this document provide the same functionality as the Endpoint Property Service (EPS) defined in Section 11.4 of [RFC7285]. Accordingly, it is RECOMMENDED that the EPS be deprecated in favor of Property Maps. However, ALTO servers MAY provide an EPS for the benefit of legacy clients.

6.2. Impact on Resource-Specific Properties

Section 10.8 of [RFC7285] defines two categories of endpoint properties: "resource-specific" and "global". Resource-specific
property names are prefixed with the ID of the resource they depend upon, while global property names have no such prefix. The property map resources defined in this document do not distinguish between those two types of properties. Instead, if there is a dependency, it is indicated by the "uses" capability of a property map, and is shared by all properties and entity domains in that map. Accordingly, it is RECOMMENDED that resource-specific endpoint properties be deprecated, and no new resource-specific endpoint properties be defined.

6.3. Impact on the "pid" Property

Section 7.1.1 of [RFC7285] defines the resource-specific endpoint property "pid", whose value is the name of the PID containing that endpoint. For compatibility with legacy clients, an ALTO server which provides the "pid" property via the Endpoint Property Service MUST use that definition, and that syntax, in the EPS resource.

However, when used with Property Maps, this document amends the definition of the "pid" property as follows.

First, the name of the property is simply "pid"; the name is not prefixed with the resource ID of a network map. The "uses" capability of the property map resource indicates the associated network map. This implies that a property map can only return the "pid" property for one network map; if an ALTO server provides several network maps, it MUST provide a property map resource for each one.

Second, a client MAY request the "pid" property for a block of addresses. An ALTO server determines the value of "pid" for an address block C as follows. Let CS be the set of all address blocks in the network map. If C is in CS, then the value of "pid" is the name of the PID associated with C. Otherwise, find the longest block C' in CS such that C' prefix-matches C, but is shorter than C. If there is such a block C', the value of "pid" is the name of the PID associated with C'. If not, then "pid" has no value for block C.

Note that although an ALTO server MAY provide a GET-mode property map resource which returns the entire map for the "pid" property, there is no need to do so, because that map is simply the inverse of the network map.
6.4. Impact on Other Properties

In general, there should be little or no impact on other previously defined properties. The only consideration is that properties can now be defined on blocks of addresses, rather than just individual addresses, which might change the semantics of a property.

7. Examples

7.1. Network Map

The examples in this section use a very simple default network map:

```
defaultpid:  ipv4:0.0.0.0/0  ipv6:::0/0
pid1:        ipv4:192.0.2.0/25
pid2:        ipv4:192.0.2.0/28  ipv4:192.0.2.16/28
```

Figure 3: Example Network Map

7.2. Property Definitions

The examples in this section use four additional properties, "ISP", "ASN", "country" and "state", with the following values:

```
<table>
<thead>
<tr>
<th>IP Address</th>
<th>ISP</th>
<th>ASN</th>
<th>Country</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4:192.0.2.0/24</td>
<td>BitsRus</td>
<td>-</td>
<td>us</td>
<td>-</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/28</td>
<td>-</td>
<td>12345</td>
<td>-</td>
<td>NJ</td>
</tr>
<tr>
<td>ipv4:192.0.2.16/28</td>
<td>-</td>
<td>12345</td>
<td>-</td>
<td>CT</td>
</tr>
<tr>
<td>ipv4:192.0.2.0/28</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>PA</td>
</tr>
</tbody>
</table>
```

Figure 4: Example Property Values

7.3. Information Resource Directory (IRD)

The following IRD defines the relevant resources of the ALTO server. It provides two Property Map resources, one for the "ISP" and "ASN" properties, and another for the "country" and "state" properties. The server could have provided a Property Map resource for all four properties, but did not, presumably because the organization that runs the ALTO server believes any given client is not interested in all four properties.

The server provides two Filtered Property Maps. The first returns all four properties, and the second just returns the "pid" property for the default network map.

The Filtered Property Maps for the "ISP", "ASN", "country" and
"state" properties do not depend on the default network map (it does not have a "uses" capability), because the definitions of those properties do not depend on the default network map. The Filtered Property Map for the "pid" property does have a "uses" capability for the default network map, because that defines the values of the "pid" property.

Note that for legacy clients, the ALTO server provides an Endpoint Property Service for the "pid" property for the default network map.

```
"meta": { ... },
"resources": {
  "default-network-map": {
    "uri": "http://alto.example.com/networkmap",
    "media-type": "application/alto-networkmap+json"
  },
  .... property map resources ....
  "country-state-property-map": {
    "uri": "http://alto.example.com/propmap/full/inet-cs",
    "media-type": "application/alto-propmap+json",
    "capabilities": {
      "domain-types": [ "ipv4", "ipv6" ],
      "prop-types": [ "country", "state" ]
    }
  },
  "isp-asn-property-map": {
    "uri": "http://alto.example.com/propmap/full/inet-ia",

    "accepts": "application/alto-propmapparams+json",
    "capabilities": {
      "domain-types": [ "ipv4", "ipv6" ],
      "prop-types": [ "ISP", "ASN", "country", "state" ]
    }
  }
```
Figure 5: Example IRD

7.4. Property Map Example

The following example uses the properties and IRD defined above to retrieve a property map for entities with the "ISP" and "ASN" properties. Note that the response does not include the entity "ipv4:192.0.2.0", because it does not have a value for either of those properties. Also note that the entities "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28" are refinements of "ipv4:192.0.2.0/24", and hence inherit its value for "ISP" property. But because that value
is inherited, it is not explicitly listed in the property map.

GET /propmap/full/inet-ia HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
  "property-map": {
    "ipv4:192.0.2.0/24": {"ISP": "BitsRus"},
    "ipv4:192.0.2.0/28": {"ASN": "12345"},
    "ipv4:192.0.2.16/28": {"ASN": "12345"}
  }
}

7.5. Filtered Property Map Example #1

The following example uses the Filtered Property Map resource to request the "ISP", "ASN" and "state" properties for several IPv4 addresses. Note that the value of "state" for "ipv4:192.0.2.0" is the only explicitly defined property; the other values are all derived by the inheritance rules for Internet address entities.
POST /propmap/lookup/inet-iacs HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: ###
Content-Type: application/alto-propmapparams+json

{
    "entities" : [ "ipv4:192.0.2.0",
                  "ipv4:192.0.2.1",
                  "ipv4:192.0.2.17" ],
    "properties" : [ "ISP", "ASN", "state" ]
}

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
7.6. Filtered Property Map Example #2

The following example uses the Filtered Property Map resource to request the "ASN", "country" and "state" properties for several IPv4 prefixes. Note that none of the returned property values is explicitly defined; all values are derived by the inheritance rules for Internet address entities.

Also note the "ASN" property has the value "12345" for both the blocks "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28", so every address in the block "ipv4:192.0.2.0/27" has that property value. However the block "ipv4:192.0.2.0/27" itself does not have a value for "ASN": address blocks cannot inherit properties from blocks with longer prefixes, even if every such block has the same value.
HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
  "property-map": {
    "ipv4:192.0.2.0/26": {"country": "us"},
    "ipv4:192.0.2.0/27": {"country": "us"},
    "ipv4:192.0.2.0/28": {
      "ASN": "12345",
      "country": "us",
      "state": "NJ"
    }
  }
}

7.7. Filtered Property Map Example #3

The following example uses the Filtered Property Map resource to request the "pid" property for several IPv4 addresses and prefixes.

Note that the value of "pid" for the prefix "ipv4:192.0.2.0/26" is "pid1", even though all addresses in that block are in "pid2", because "ipv4:192.0.2.0/25" is the longest prefix in the network map which prefix-matches "ipv4:192.0.2.0/26", and that prefix is in "pid1".
7.8. Filtered Property Map Example #4

The following example uses the Filtered Property Map resource to request the "availbw" property for several abstract network elements.
POST /propmap/lookup/availbw HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: ###
Content-Type: application/alto-propmapparams+json

{
    "entities" : [
        "ane:L001",
        "ane:Lae0",
        "ane:L3eb 
    ],
    "properties" : [ "availbw" ]
}

HTTP/1.1 200 OK
Content-Length: ###
Content-Type: application/alto-propmap+json

{
    "property-map": {
        "ane:L001": {"availbw": "55"},
        "ane:Lae0": {"availbw": "70"},
        "ane:L3eb": {"availbw": "40"}
    }
}

8. Security Considerations

As discussed in Section 15 of [RFC7285], properties MAY have sensitive customer-specific information. If this is the case, an ALTO Server MAY limit access to those properties by providing several different Property Maps. For non-sensitive properties, the ALTO Server would provide a URI which accepts requests from any client. Sensitive properties, on the other hand, would only be available via a secure URI which would require client authentication.

Also, while technically this document does not introduce any security risks not inherent in the Endpoint Property Service defined by [RFC7285], the GET-mode property map resource defined in this document does make it easier for a client to download large numbers of property values. Accordingly, an ALTO Server SHOULD limit GET-mode Property Maps to properties which do not contain sensitive data.
9. IANA Considerations

This document defines additional application/alto-* media types, and extends the ALTO endpoint property registry.

9.1. application/alto-* Media Types

This document registers two additional ALTO media types, listed in Table 1.

<table>
<thead>
<tr>
<th>Type</th>
<th>Subtype</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>application</td>
<td>alto-propmap+json</td>
<td>Section 4.1</td>
</tr>
<tr>
<td>application</td>
<td>alto-propmapparams+json</td>
<td>Section 5.3</td>
</tr>
</tbody>
</table>

Table 1: Additional ALTO Media Types.

Type name: application

Subtype name: This document registers multiple subtypes, as listed in Table 1.

Required parameters: n/a

Optional parameters: n/a

Encoding considerations: Encoding considerations are identical to those specified for the "application/json" media type. See [RFC7159].

Security considerations: Security considerations related to the generation and consumption of ALTO Protocol messages are discussed in Section 15 of [RFC7285].

Interoperability considerations: This document specifies formats of conforming messages and the interpretation thereof.

Published specification: This document is the specification for these media types; see Table 1 for the section documenting each media type.
Applications that use this media type: ALTO servers and ALTO clients either stand alone or are embedded within other applications.

Additional information: ~ Magic number(s): ~ n/a File extension(s): ~ This document uses the mime type to refer to protocol messages and

9.2. ALTO Entity Domain Registry

This document requests IANA to create and maintain the "ALTO Entity Domain Registry", listed in Table 2.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Entity Address Encoding</th>
<th>Hierarchy &amp; Inheritance</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4</td>
<td>See Section 3.1.1</td>
<td>See Section 3.1.3</td>
</tr>
<tr>
<td>ipv6</td>
<td>See Section 3.1.2</td>
<td>See Section 3.1.3</td>
</tr>
<tr>
<td>pid</td>
<td>See Section 3.2</td>
<td>None</td>
</tr>
<tr>
<td>ane</td>
<td>See Section 3.4</td>
<td>None</td>
</tr>
</tbody>
</table>

Table 2: ALTO Entity Domain Names.

This registry serves two purposes. First, it ensures uniqueness of identifiers referring to ALTO entity domains. Second, it states the requirements for allocated domain names.
New ALTO entity domains are assigned after IETF Review [RFC5226] to ensure that proper documentation regarding the new ALTO entity domains and their security considerations has been provided. RFCs defining new entity domains SHOULD indicate how an entity in a registered domain is encoded as an EntityName, and, if applicable, the rules defining the entity hierarchy and property inheritance. Updates and deletions of ALTO entity domains follow the same procedure.

Registered ALTO entity domain identifiers MUST conform to the syntactical requirements specified in Section 2.3. Identifiers are to be recorded and displayed as strings.

Internet-Draft Unified Properties December 2017

It is RECOMMENDED that a new ALTO entity domain be registered when the corresponding address type is registered based on ALTO Address Type Registry [RFC7285].

Requests to add a new value to the registry MUST include the following information:

- **Identifier**: The name of the desired ALTO entity domain.
- **Entity Address Encoding**: The procedure for encoding the address of an entity of the registered type as an EntityAddr (see Section 2.4).
- **Hierarchy**: If the entities form a hierarchy, the procedure for determining that hierarchy.
- **Inheritance**: If entities can inherit property values from other entities, the procedure for determining that inheritance.
- **Security Considerations**: In some usage scenarios, entity addresses carried in ALTO Protocol messages MAY reveal information about an ALTO client or an ALTO service provider. Applications and ALTO service providers using addresses of the registered type SHOULD be made aware of how (or if) the addressing scheme relates to private information and network proximity.

This specification requests registration of the identifiers "ipv4", "ipv6" and "pid", as shown in Table 2.
9.3. ALTO Endpoint Property Type Registry

The ALTO Endpoint Property Type Registry was created by [RFC7285]. If possible, the name of that registry SHOULD be changed to "ALTO Entity Property Type Registry", to indicate that it is not restricted to Endpoint Properties. If it is not feasible to change the name, the description MUST be amended to indicate that it registers properties in all domains, rather than just the Internet address domain.
