Definitions of Supplemental Managed Objects for ATM Interface

January 3, 2003

draft-ietf-atommib-atm2-19.txt

Status of this Memo

Copyright Notice

Abstract

This memo defines objects used for managing ATM-based interfaces, devices,

and services in addition to those defined in the ATM-MIB [24], to provide additional support for the management of:

- ATM Switched Virtual Connections (SVCs)
- ATM Permanent Virtual Connections (PVCs)

1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

2. Overview

The purpose of this memo is to provide additional capabilities, not found in the ATM-MIB [24], which are needed to manage ATM interfaces. This memo addresses the following areas:

- ATM Switch Support
- ATM Service Support
- ATM Host Support

In addition, this memo also provides ATM trap support.

2.1 Background

In addition to the MIB module defined in this memo, other MIB modules are necessary to manage ATM interfaces, links and cross-connects. Examples include MIB II for general system and interface management (RFC 1907 [5] and RFC 2863 [4]), the DS3 (RFC 2496 [31]) or SONET MIBs (RFC 2558 [30]) for management of SONET and DS3 physical interfaces, and, as appropriate, MIB modules for applications that make use of ATM, such as SMDS [28] and LAN Emulation [27]. These MIB modules are outside the scope of this specification.

This MIB module also requires the use of the ATM-MIB module defined in [24] and ATM-specific textual conventions defined in [34].

ATM Endpoint applications such as ATM LAN Emulation or Classical

IP-over-ATM Clients and Servers use ATM to establish SVC/PVC connections for exchanging control and data information. The agents of these ATM applications must provide the network manager with information on the SVC/PVCs in use and which applications are using them. The information can be made generic so as to apply to all ATM applications. This memo defines extensions to the ATM-MIB [24] in order to support this.

The current specification of this supplemental ATM2-MIB is based on SNMPv2 SMI.

2.2 Important Definitions

The following terms are defined here and used throughout this MIB:

- Virtual Path Link (VPL)
- Virtual Path Connection (VPC)
- Virtual Path Segment (VP Segment)
- Virtual Channel Link (VCL)
- Virtual Channel Connection (VCC)
- Virtual Channel Segment (VC Segment).

The figures on the next page show how these terms apply in typical ATM network topologies. Additional terms relevant to this MIB are defined and illustrated in the ATM Terminology section 3 of [24].

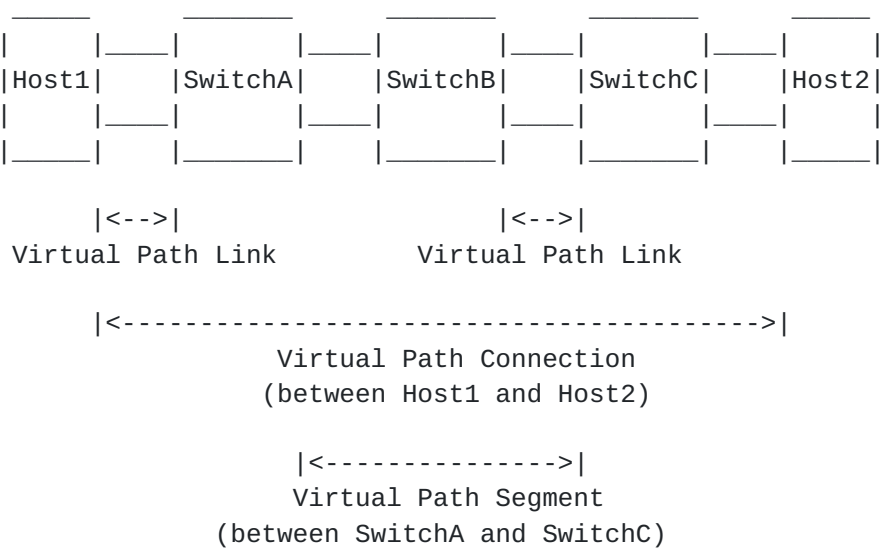

Figure 1: Examples of Virtual Path Links, Virtual Path Connection, and Virtual Path Segment

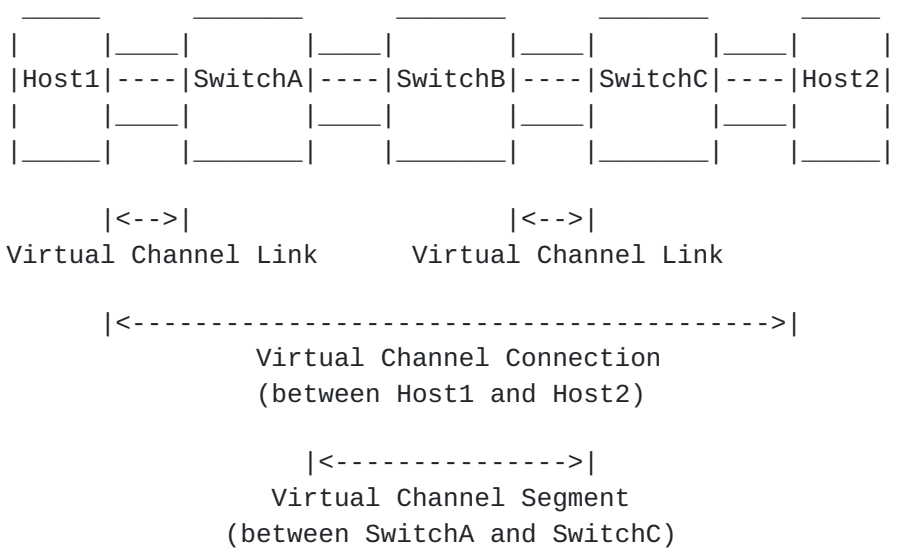

Figure 2: Examples of Virtual Channel Links, Virtual Channel Connection, and Virtual Channel Segment

3. Conventions used in the MIB

3.1 Structure

The managed ATM objects are arranged as follows:

Table	Host	Switch	Service
atmSvcVcCrossConnectTable		Y	Y
atmSvcVpCrossConnectTable		Y	Y
atmSigStatTable	Y	Y	Y
atmSigSupportTable		Y	Y
atmSigDescrParamTable	Y		
atmIfRegisteredAddrTable		Y	Y
atmVclAddrTable	Y		
atmAddrVclTable	Y		
atmVplStatTable	Y	Y	Y
atmVplLogicalPortTable	Y	Y	Y
atmVclStatTable	Y	Y	Y
atmAal5VclStatTable	Y		
atmVclGenTable	Y		

atmInterfaceExtTable	Y	Y	Y
atmIlmiSrvcRegTable		Y	Y
atmIlmiNetworkPrefixTable		Y	Y
atmSwitchAddressTable		Y	
atmVpCrossConnectXTable			Y
atmVcCrossConnectXTable			Y
atmCurrentlyFailingPVplTable	Y	Y	Y
atmCurrentlyFailingPVclTable	Y	Y	Y

Table 1: MIB structure

3.1.1 ATM SVC VP Cross-Connect Table

This table provides the SVC VP Cross-Connect (SVPC) information. The equivalent PVC VP Cross-Connect table is defined in [24]. This table also includes cross-connect information for Soft PVPs.

This table contains configuration and state information of all SVC VP point-to-point, point-to-multipoint, or multipoint-to-multipoint VP cross-connects.

This table has read-only access and can be used to monitor the cross-connects which connect the VPLs together in an ATM switch or network. The atmSvcVpCrossConnectIndex is used to associate the related SVC VPLs that are cross-connected together. The atmSvcVpCrossConnectRowStatus object has read-write access to allow for tear-down.

The ATM SVC VP Cross-Connect Table models each bi-directional Switched Virtual Circuit (SVC) VP cross-connect as a set of entries in the atmSvcVpCrossConnectTable. A point-to-point VPC cross-connect is modeled as one entry; a point-to-multipoint (N leafs) VPC cross-connect as N entries in this table; and a multipoint-to-multipoint (N parties) VPC cross-connect as N(N-1)/2 entries in this table. In the latter cases, all the N (or N(N-1)/2) entries are associated with a single VPC cross-connect by having the same value of atmSvcVpCrossConnectIndex.

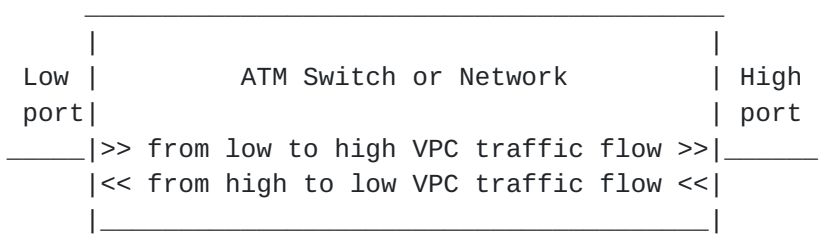

Figure 3: VPC Cross-Connect Model

The terms low and high are chosen to represent numerical ordering of the two interfaces associated with a VPC cross-connect. That is, the ATM interface with the lower value of ifIndex is termed 'low', while the other ATM interface associated with the VPC cross-connect is termed 'high'.

3.1.2 ATM SVC VC Cross-Connect Table

This table provides the SVC Cross-Connect (SVCC) information. The equivalent PVC VC Cross-Connect table is defined in [24]. This table also includes cross-connect information for Soft PVCs.

This table is used to model a bi-directional point-to-point, point-to-multipoint or multipoint-to-multipoint SVC VC cross-connect.

This table has read-only access and is used to monitor the cross-connects which connect the VCLs together in an ATM switch or network that belong to a VC connection. The atmSvcVcCrossConnectIndex is used to associate the related SVC VCLs that are cross-connected together. The atmSvcVcCrossConnectRowStatus object has read-write access to allow for tear-down.

The ATM SVC VC Cross-Connect Table models each bi-directional Switched Virtual Circuit (SVC) VC cross-connect as a set of entries in the atmSvcVcCrossConnectTable. A point-to-point VC cross-connect is modeled as one entry; a point-to-multipoint (N leafs) VC cross-connect as N entries in this table; and a multipoint-to-multipoint (N parties) VPC cross-connect as N(N-1)/2 entries in this table. In the latter cases, all the N (or N(N-1)/2) entries are associated with a single VPC cross-connect by having the same value of atmSvcVcCrossConnectIndex.

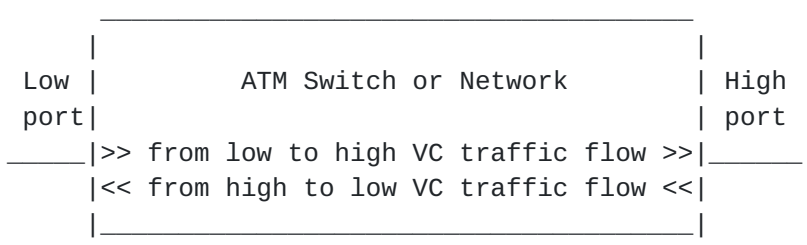

Figure 4: VC Cross-Connect Model

The terms low and high are chosen to represent numerical ordering of the two interfaces associated with a VPC cross-connect. That is, the ATM interface with the lower value of ifIndex is termed 'low', while the other ATM interface associated with the VPC cross-connect is termed 'high'.

5.1.3 ATM Interface Signalling Statistics Table

This table provides statistical information of the signalling entity. A signalling entity can be deployed over an ATM interface as defined in the atmInterfaceConfTable [24], a logical ATM interface defined in section 5.1.10.1 in this document, or a proprietary virtual interface as described in the atmInterfaceExtTable. To monitor the signalling entity, a few counters are provided. They are defined as:

atmSigSSCOPConEvents
atmSigSSCOPErrdPdus
atmSigDetectSetupAttempts
atmSigEmitSetupAttempts
atmSigDetectUnavailRoutes
atmSigEmitUnavailRoutes
atmSigDetectUnavailResrcs
atmSigEmitUnavailResrcs
atmSigDetectCldPtyEvents
atmSigEmitCldPtyEvents
atmSigDetectMsgErrors
atmSigEmitMsgErrors
atmSigDetectClgPtyEvents
atmSigEmitClgPtyEvents
atmSigDetectTimerExpireds
atmSigEmitTimerExpireds
atmSigDetectRestarts
atmSigEmitRestarts
atmSigInEstabls
atmSigOutEstabls

3.1.4 ATM Signalling Capability Support

A number of Information Elements may or may not be supported by ATM switches or ATM Services. Hence, for trouble isolation it is important to keep track which particular Information Elements are supported. The corresponding group of objects must be supported by switches or services supporting SVCs, and indicate whether the following Information Elements are enabled/disabled:

1) Calling party number

2) Calling party subaddress

3) Called party subaddress

4) Broadband high layer information

5) Broadband low layer information

5) Broadband Repeat Indicator

7) AAL parameters

The last parameter, Preferred Carrier Pre-Subscription, identifies the carrier to which intercarrier calls originated from this interface are routed when transit network selection information is not provided by the calling party.

5.1.5 Signalling Descriptor Parameter Table

This table extends the ATM VCL table of the ATM-MIB [24] to include all other necessary signalling information as specified in the ATM Forum UNI Specifications [25] and [26]. A user can create an entry with all signalling parameters and later use that entry to specify the signalling characteristics of SVCs.

Some of the signalling parameters, such as the AAL5 parameters information element, are reflected in the VCL and VPL tables, and this table only contains the remaining AAL5 parameters.

Signalling attributes can be grouped into following categories:

1) ATM Adaptation Layer Parameters

Information in this group is captured in the ATM Signalling Descriptor Parameter Table defined in this memo. Please refer to section 5.4.5.5 of [25] and [26].

2) Broadband High Layer Information

Information in this group is captured by the ATM Signalling Descriptor Parameter Table defined in this memo. Please refer to section 5.4.5.8 of [25] and [26].

3) Broadband Low Layer Information

Information in this group is captured by the ATM Signalling Descriptor Parameter Table defined in this memo. Please refer to section 5.4.5.9 of [25] and [26].

3.1.6 ATM Interface Registered Address Table

This table contains a list of ATM addresses that can be used for calls to and from a given interface by a switch or service. The ATM addresses are either registered by the endsystem via ILMI or statically configured. This table does not expose PNNI reachability information. This table only applies to switches and network services. See also Section 5.2.

3.1.7 ATM VPI/VCI to Address Mapping Table

In the atmVclAddrTable, the object atmVclAddrAddr can either be an ATM Local Address or an ATM Remote Address which represent the two endpoint addresses of a VCL. ATM Local Address identifies the local endpoint of the VCL represented by this agent. The ATM Remote address represents the address of the ATM application at the other end of the VCL.

5.1.8 ATM Address to VPI/VCI Mapping Table

This table provides an alternative way to retrieve the atmVclTable. This table can be used to retrieve the indexing to the atmVclTable by an ATM address.

3.1.9 ATM VPL Statistics Table

The atmVplStatTable includes per-VPL cell counters. The VPL cell counters count the valid ATM cells. The valid ATM cells include the user and OAM cells but exclude the physical layer (e.g., idle cells) and unassigned cells.
Cells coming into an ATM managed system are counted differently with the high Cell Loss Priority (CLP=0) or low Cell Loss Priority (CLP=1). The cells are tagged, passed or discarded depending on the incoming CLP value and the policed cell rate by the "traffic policing" entity in the ATM managed system. Refer to [25] and [26] for a description of the traffic policing.

In the switch where the traffic policing is not supported, cells are passed or discarded depending on the bandwidth and buffering capacity of the switching fabric.
The Output Tagged Cells counter, in this case, is always zero.

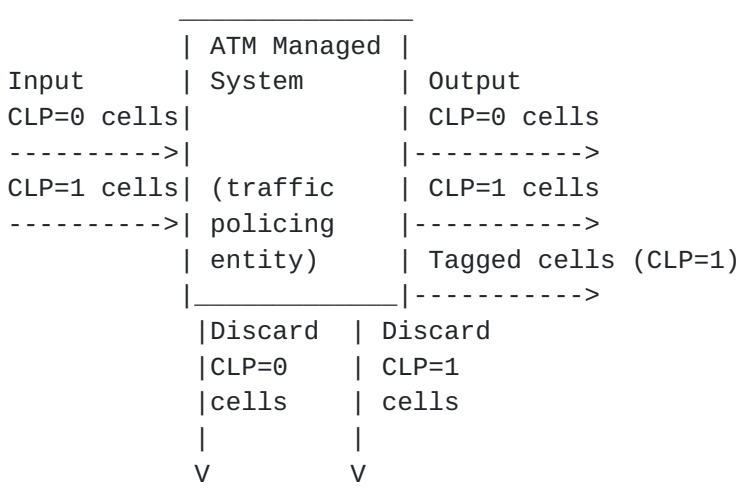

Figure 5: ATM Cell Counters per VPL

In this table, cells coming into and out of the managed ATM system are counted as the total number of cells and the cells with the CLP=0. The CLP=1 counter is derived by subtracting CLP=0 cells from the total cells. In addition, cells that are tagged on the output are also counted. The output CLP=1 cells equals the total cells out count minus both the CLP=0 cells and the tagged cells.

3.1.10 ATM VPL Logical Port Table

The ATM VPL Logical Port Table includes all ATM logical port interface configuration information.

3.1.10.1 ATM Logical Port Interface

The interface type "ATM Logical Port" (ifType=80) is defined to allow the representation of a VP Tunnel, which is a VPL used as a trunk connection (most likely between devices that are not physically adjacent), providing for multiplexing and demultiplexing of VCs on the VP. Figure 6 illustrates such a VP Tunnel.

Note: the "ATM Logical Port" interface is more of a logical port, compared with an interface of type "ATM" which is more of a physical port that provides for the transport of many VP and VC connections between adjacent devices.

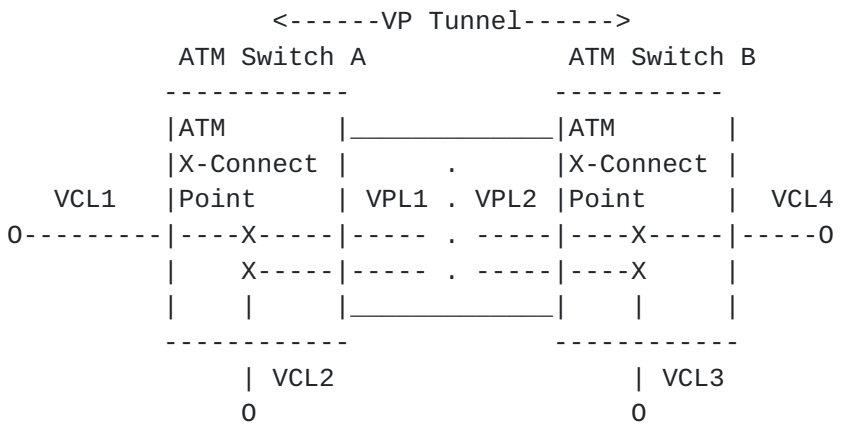

Figure 6: Virtual Path Tunnel

In Figure 6, a VP tunnel (denoted as VPL1 by Switch A, and as VPL2 by Switch B) is used to connect VCL1 with VCL4 and VCL2 with VCL3. Figure 6 shows only one VP tunnel, but there can be multiple VP tunnels over the same physical interface.

A particularly useful VP tunnel scenario is tunneling across a public network that does not support signalling. In Figure 6 above, assume Switches A and B are private switches that signal over the VP to set up connections transparently through the public network. The public network would just transport a PVC VP between the two switches.

Because the VP Tunnel constitutes an interface between two ATM devices that are not necessarily physically adjacent, most of the management information pertaining to the interface may differ for the tunnel, including:

- active VPI/VCI fields (the tunnel may be a subset of the parent interface).
- maximum number of VCCs
- configured VCCs
- ILMI VPI/VCI values
- ATM address type
- ATM administrative address
- received/transmitted cells.

3.1.10.2 How to create an ATM Logical Port interface

On ATM devices supporting VP tunnels, the ATM Logical Port Interface Table can be used to create VP tunnels. To create an ATM Logical Port interface via SNMP:

- Create a VPL (e.g., VPI=a on an existing ATM interface which has ifIndex=x) in the atmVplTable.

- Set the object atmVplLogicalPortDef to isLogicalIf. A new row in the ifTable is then created by the agent, with ifIndex=y, to represent the ATM Logical Port interface. The object atmVplLogicalPortIndex is also set to y by the agent to represent the ifIndex value of the ATM Logical Port interface.

- The ifEntry values are set for the ATM Logical Port interface (ifIndex=y) as discussed in RFC 2515, with the following exceptions:
    * ifType - a new enumerated value of atmLogical(80) was added to IANAifType, specifying an "ATM Logical Port" interface.
    * ifSpeed - The total bandwidth in bits per second for use by the ATM layer. Computed from the traffic descriptor for the VPL.
    * ifOperStatus - determined hierarchically, depending on the state of the physical atm-cell layer interface beneath it, and the ILMI on the VP.
    * ifInOctets, ifOutOctets - support of these objects is not mandatory for ATM Logical Port interfaces.
    * ifInErrors - always zero, HEC errors are specified for the atm cell-layer interface beneath it.
    * ifInUnknownProtos - always zero, errors are specified for the atm cell-layer interface beneath it.

- The atmInterfaceConfEntry values are set and reported as discussed in [24], with the following exceptions:
    * atmInterfaceMaxVpcs - 0.
    * atmInterfaceConfVpcs - 0.
    * atmInterfaceIlmiVpi - VPI of the VP tunnel.

- The atmInterfaceExtEntry values are set and reported as follows:
    * atmInterfaceConfMaxSvpcVpi - VPI of the VP tunnel, although VPCs cannot be setup on a VP tunnel.
    * atmInterfaceCurrentMaxSvpcVpi - VPI of VP tunnel, although VPCs cannot be setup on a VP tunnel.
    * atmInterfaceConfMaxSvccVpi - VPI of the VP tunnel.
    * atmInterfaceCurrentMaxSvccVpi - VPI of VP tunnel.
    * atmIntfPvcFailures - Includes failures of PVCLs

within the VP tunnel, but not of the PVPL itself, since those are reported on the atm(37) interface.
* atmIntfCurrentlyFailingPVpls - 0.
* atmIntfPvcFailuresTrapEnable - Enables traps for PVCL failures within the VP tunnel, but not for the PVPL itself, since the latter are generated on behalf of the atm(37) interface.

- An entry is created in the ifStackTable, with values: ifStackHigherLayer=y, ifStackLowerLayer=x.

- VCLs defined on the VP tunnel are indexed by ifIndex=y, VPI=a, VCI.

3.1.11 ATM VCL Statistics Table

The atmVclStatTable includes per-VCL cell counters. The VCL cell counters count the valid ATM cells. The valid ATM cells include the user and OAM cells but exclude the physical layer (e.g., idle cells) and unassigned cells.
Cells coming into an ATM managed system are counted differently with the high Cell Loss Priority (CLP=0) or low Cell Loss Priority (CLP=1). The cells are tagged, passed or discarded depending on the incoming CLP value and the policed cell rate by the "traffic policing" entity in the ATM managed system. Refer to [25] and [26] for the description of the traffic policing.

In a switch where the traffic policing is not supported, cells are passed or discarded depending on the bandwidth and buffering capacity of the switching fabric.
The Output Tagged Cells counter, in this case, is always zero.

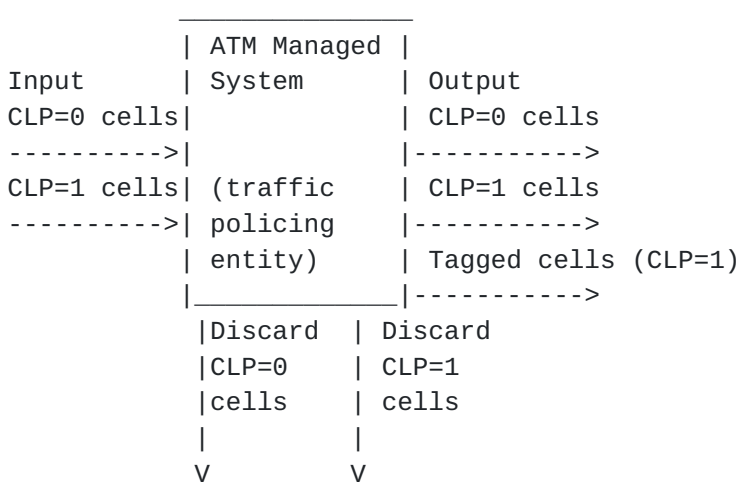

Figure 7: ATM Cell Counters per VCL

In this table, cells coming into and out of the managed ATM system are counted as the total number of cells and the cells with the CLP=0. The CLP=1 counter is derived by subtracting CLP=0 cells from the total cells. In addition, cells that are tagged on the output are also counted. The output CLP=1 cells equals the total cells out count minus both the CLP=0 cells and the tagged cells.

3.1.12 ATM VC General Information Table

This table contains the general information for each VC. It provides an index to the atmSigDescrParamTable defined in this MIB. This table is an extension to the atmVclTable defined in the ATM-MIB [24].

3.1.13 ATM Interface Configuration Extension Table

The ATM Interface Configuration Extension Table contains ATM interface information that supplements the atmInterfaceConfTable defined in [24]. It includes the configuration information of the interface type (i.e., connection setup procedures) and ILMI.

A network manager can configure the interface to run a specific type of connection setup procedures (i.e., protocol and version) such as ITU-T DSS2, ATM Forum UNI 3.1, PNNI 1.0 or BICI 2.0. It can also dictate the role of the managed entity as one side of the interface. For example, if an interface is configured to run ATM Forum UNI 3.1, the managed entity has to be told to run as either the network side or the user side of the UNI.

The objects atmIntfConfigType and atmIntfConfigSide are used for configuration and the objects atmIntfActualType and atmIntfActualSide

are used for reading back the actual interface protocol and version.

The following table describes all the valid combinations of configuration of the interface type and side. Note that the value N/A meaning not applicable, should be set to the value other(1) when used.

atmIntfConfigType	atmIntfConfigSide
autoConfig	N/A
ituDss2	user/network
atmfUni3Dot0	user/network
atmfUni3Dot1	user/network
atmfUni4Dot0	user/network
atmfIispUni3Dot0	user/network
atmfIispUni3Dot1	user/network
atmfIispUni4Dot0	user/network
atmfPnni1Dot0	N/A
atmfBici2Dot0	N/A
atmfUniPvcOnly	user/network
atmfNniPvcOnly	N/A

When the value of the object atmIntfConfigType is configured to autoConfig(2), the interface type is determined via the ATM Forum ILMI auto-configuration procedures [29]. There is no need to set the interface side since it should be a derived value. The PNNI and BICI interfaces are always symmetric so setting the interface side is also not necessary.

This table also includes the configured and negotiated maximum VPI value per ATM interface, and the configured and negotiated minimum VCI value per ATM interface. Refer to [29] Sections 8.2.3.8 through 8.2.3.10 for a detailed description.

The following figure provides an example how the current minimum VCI values are derived from the configured minimum VCI values and the neighboring minimum VCI values:

ifA: Configured Min SVCC VCI = 32 (configured)
Current Min SVCC VCI = 40 (negotiated)

ifB: Configured Min SVCC VCI = 40 (configured)
Current Min SVCC VCI = 40 (negotiated)

ifC: Configured Min SVCC VCI = 32 (configured)
Current Min SVCC VCI = 32 (negotiated)

ifD: Configured Min SVCC VCI = 32 (configured)
Current Min SVCC VCI = 32 (negotiated)

Between ifA and ifB, the maximum of the two vales for atmInterfaceConfMinSvccVci is 40, so both interfaces set their atmInterfaceCurrentMinSvccVci values to 40. On the other hand, since ifC and ifD both are configured with atmInterfaceConfMinSvccVci values of 32, they set their atmInterfaceCurrentMinSvccVci values to 32.

Figure 8: Examples of configured vs. negotiated ILMI values

3.1.14 ATM ILMI Service Registry Table

This table contains information used by the switch/service to inform ATM hosts of the location of ATM network services such as the LAN Emulation Configuration Server (LECS), the ATM Name Server (ANS), the ATMARP Server, the Multicast Address Resolution Server (MARS), and the NHRP Server (NHS).
Entries in this table are exported to adjacent devices via ILMI over either all or a few user selected ATM interfaces.

As an example, let's assume that:
- An ATM switch X has three interfaces if1, if2 and if3.
- There are two ATM network services offered, a1.a2...aN and b1.b2...bN, where a1.a2...aN is an object identifier used to identify the first service, and b1.b2...bN is the object identifier for the other service.
- The first service is available at the ATM address 'a'.
- The second service is available at the ATM address 'b'.
- The first service can be used by any device connecting to

the switch X.

- The second service can be used only by devices that connect to interfaces if1 and if3 on switch X.

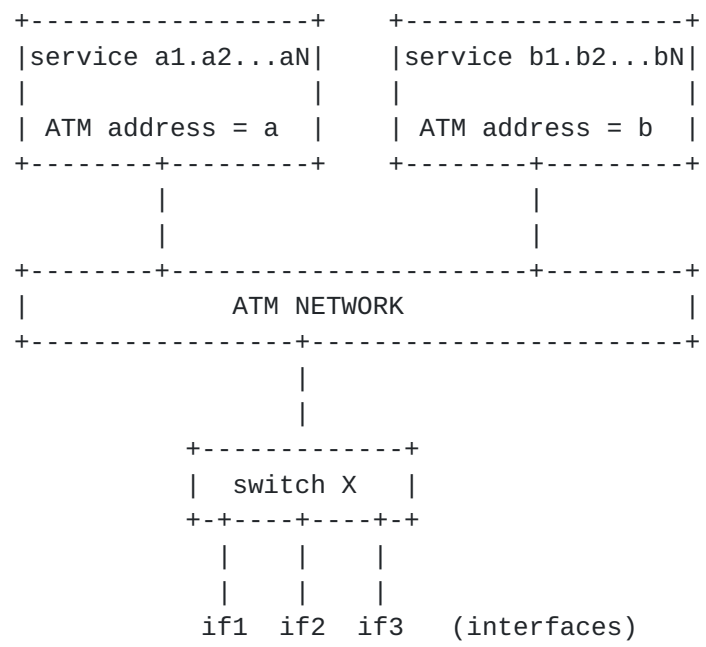

Figure 9: ATM topology with registered services

The table for switch X will contain three entries:
- one entry for the "a1.a2...aN", implicitly available to any devices on switch X.
- two entries for the "b1.b2...bN" (one for each interface where this service can be explicitly used).

The content of the table is:

- Service Identifier:	a1.a2...aN	b1.b2...bN	b1.b2...bN
- ATM address:	a	b	b
- Arbitrary index:	m	n	p
- Available interface:	0	1	3

where the Service Identifier values a1.a2...aN and b1.b2...bN are represented by atmIlmiSrvcRegServiceID, the ATM addresses a and b are represented by atmIlmiSrvcRegATMAddress, the values m, n, and p are arbitrary non-zero integer parameters (necessary in this example to differentiate the two entries for b1.b2...bN that are both available at the ATM address 'b') represented by atmIlmiSrvcRegAddressIndex, and the available interfaces are represented by atmIlmiSrvcRegIndex, where the special value 0 indicates any ATM interface.

When querying the ILMI service registry table, through the ILMI protocol:
- the device attached to interface if1 will obtain the address a and b.

- the device attached to interface if2 will obtain the address a only.
- the device attached to interface if3 will obtain the address a and b.

3.1.15 ILMI Network Prefix Table

A table specifying per-interface network prefix(es) supplied by the network side of the UNI during ILMI address registration. When no network prefixes are specified for a particular interface, one or more network prefixes based on the switch address(es) may be used for ILMI address registration.

3.1.16 ATM Switch Address Table

This table contains one or more ATM endsystem addresses on a per-switch basis. These addresses are used to identify the switch. When no ILMI network prefixes are configured for certain interfaces, network prefixes based on the switch address(es) may be used for ILMI address registration.

3.1.17 AAL5 per-VCC Statistics Table

This table contains the AAL5 statistics for the VCCs.

3.1.18 ATM VP Cross-Connect Extension Table

This table extends the atmVpCrossConnectTable defined in ATM-MIB [24].

3.1.19 ATM VC Cross-Connect Extension Table

This table extends the atmVcCrossConnectTable defined in ATM-MIB [24].

3.1.20 Currently Failing PVPL Table

This table contains all the PVPLs that are in trouble.

3.1.21 Currently Failing PVCL Table

This table contains all the PVCLs that are in trouble.

3.1.22 Leaf Initiated Join Counter support

Two counter objects are added to count the number of leaf intiated setup requests and setup failures.

3.2 Network and User Addresses

At the user side of a given ATM UNI interface there may be an address, "ifPhysAddress", to identify the interface. In addition, there may be several other addresses which can be used to originate and receive calls. These other addresses that are used to receive calls are listed in the "ifRcvAddrTable" defined in RFC 2863 [4]. The registered addresses on the network side are listed in the ATM Registered Address Table. The ATM Registered Address Table is supported by switches and network services. It is not supported by hosts.

3.3 Configuration of VPLs, VCLs, and Cross-Connects

The ATM Managed Objects needed to support the configuration of VPLs, VCLs, and Cross-Connects of the Permanent VPLs and VCLs are defined in the ATM-MIB [24]. Cross-Connects of the Switched VPLs and VCLs are defined in this memo.

3.4 ATM-related Trap Support

Traps are defined to detect changes in the status of permanent VPLs and VCLs. The current up/down status of each permanent VPL or VCL is indicated by the atmVplOperStatus or atmVclOperStatus object, respectively. Several tables and objects and one trap are defined in order to help network managers quickly and efficiently detect changes in the status of permanent virtual links. Through use of these tables, objects, and traps, the time consuming and resource intensive task of continuously polling each row in the entire atmVplTable and atmVclTable can be avoided.

The atmIntfPvcFailures counter and the atmIntfCurrentlyFailingPVpls and atmIntfCurrentlyFailingPVcls gauges provide a quick means of determining the status of all PVPLs and PVCLs on an interface. The atmCurrentlyFailingPVplTable and the atmCurrentlyFailingPVclTable list all of the problematic PVPLs and PVCLs, respectively, allowing them to be quickly identified.

The atmIntfPvcFailuresTrap is generated just after a PVPL or PVCL on a particular interface leaves the `up' operational state. Managers can then determine which PVPLs and/or PVCLs are failing by reading the atmCurrentlyFailingPVplTable and the atmCurrentlyFailingPVclTable. Generation of the atmIntfPvcFailuresTrap is rate limited by suppressing all traps that would occur within atmIntfPvcNotificationInterval of a previous trap for the same interface. Managers should continuously poll the tables and objects mentioned above for at least this amount of time in order to keep up with the state of the network.

4. Conformance and Compliance

See the conformance and compliance statements within the information module.

       SYNTAX       Counter32
       MAX-ACCESS   read-only
       STATUS       current
       DESCRIPTION
          "Number of Incorrect Messages detected on this interface.  The
          Incorrect Messages Counter reflects any sort of incorrect
          information in a message.  This includes:
```

- RELEASE, RELEASE COMPLETE, ADD PARTY REJECT, and STATUS messages transmitted, that contain any of the Cause values listed below.

- Ignored messages. These messages are dropped because the message was so damaged that it could not be further processed. A list of dropped messages is compiled below:

  1. Message with invalid protocol discriminator

  2. Message with errors in the call reference I.E.
     - Bits 5-8 of the first octet not equal to '0000'
     - Bits 1-4 of the first octet indicating a length other than 3 octets
     - RELEASE COMPLETE message received with a call reference that does not relate to a call active or in progress
     - SETUP message received with call reference flag incorrectly set to 1
     - SETUP message received with a call reference for a call that is already active or in progress.

  3. Message too short

The following cause values are monitored by this counter (Note: These cause values apply to both UNI3.0 and UNI3.1 unless otherwise stated):

Cause Value	Meaning
10	VPCI/VCI unacceptable (UNI3.0 only)
36	VPCI/VCI assignment failure (UNI3.1 only)
81	invalid call reference value
82	identified channel does not exist
89	invalid endpoint reference
96	mandatory information element is missing
97	message type non-existent or not implemented
99	information element non-existent or not implemented
100	invalid information element contents
101	message not compatible with call state
104	incorrect message length

```
            111    protocol error, unspecified

            NOTE:  For this counter, RELEASE COMPLETE messages that are
            a reply to a previous RELEASE message and contain the same
            cause value, are redundant (for counting purposes) and
            should not be counted."

8. Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure

environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

Table	Sensitivity/vulnerability
1. atmSvcVpCrossConnectTable	Deletion of VP cross-connects
2. atmSvcVcCrossConnectTable	Deletion of VC cross-connects
3. atmSigStatTable	Signalling read-only statistics
4. atmSigSupportTable	Signalling configuration params
5. atmSigDescrParamTable	Signalling configuration params
6. atmIfRegisteredAddrTable	Interface address table
7. atmVclAddrTable	VCL/Address mapping table
8. atmAddrVclTable	VCL/Address mapping table (read-only)
9. atmVplStatTable	VPL statistics (read-only)
10. atmVplLogicalPortTable	VPL logical port configuration
11. atmVclStatTable	VCL statistics (read-only)
12. atmAal5VclStatTable	AAL5 statistics (read-only)
13. atmVclGenTable	Signalling configuration
14. atmInterfaceExtTable	Interface configuration
15. atmIlmiSrvcRegTable	ILMI config params
16. atmIlmiNetworkPrefixTable	ILMI config params
17. atmSwitchAddressTable	Switch address info
18. atmVpCrossConnectXTable	VP cross-connect params
19. atmVcCrossConnectXTable	VC cross-connect params
20. atmCurrentlyFailingPVplTable	PVPL status info (read-only)
21. atmCurrentlyFailingPVclTable	PVCL status info (read-only)

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
