Protocol Extensions for Header Compression over MPLS

Status of this Memo

Copyright Notice

Abstract

   VoIP typically uses the encapsulation voice/RTP/UDP/IP. When MPLS
   labels are added, this becomes voice/RTP/UDP/IP/MPLS-labels. For an
   MPLS VPN, the packet header is typically 48 bytes, while the voice
   payload is often no more than 30 bytes, for example. Header
   compression can significantly reduce the overhead through various
   compression mechanisms. MPLS is used to route header-compressed (HC)
   packets over an MPLS LSP without compression/decompression cycles at
   each router. Such an HC over MPLS capability increases the bandwidth

efficiency as well as processing scalability of the maximum number of
simultaneous compressed flows that use HC at each router. MPLS
pseudowires are used to transport the HC context and other control
messages between the ingress and egress MPLS label switched router
(LSR). Standard HC methods (e.g., ECRTP, ROHC, etc.) are re-used to
determine the context. Each HC scheme operates over a single
pseudowire instance very much like it would over a single
point-to-point link.

Table of Contents

1. Introduction

Voice over IP (VoIP) typically uses the encapsulation
voice/RTP/UDP/IP. When MPLS labels [RFC3031] are added, this becomes
voice/RTP/UDP/IP/MPLS-labels. MPLS VPNs (e.g., [RFC2547]) use label
stacking, and in the simplest case of IPv4 the total packet header is
at least 48 bytes, while the voice payload is often no more than 30
bytes, for example. When IPv6 is used, the relative size of the
header in comparison to the payload is even greater. The interest in
header compression (HC) is to exploit the possibility of
significantly reducing the overhead through various compression
mechanisms, such as with enhanced compressed RTP (ECRTP) [RFC3545]
and robust header compression (ROHC) [RFC3095], and also to increase
scalability of HC. MPLS is used to route HC packets over an MPLS

label switched path (LSP) without compression/decompression cycles
at each router. Such an HC over MPLS capability can increase
bandwidth efficiency as well as the processing scalability of the

maximum number of simultaneous compressed flows that use HC at each
router. Goals and requirements for HC over MPLS are discussed in
[RFC4247]. The solution put forth in this document using MPLS
pseudowire (PW) technology has been designed to address these goals
and requirements.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in [RFC2119].

Context: the state associated with a flow subject to IP header
compression. While the exact nature of the context is specific to a
particular HC protocol (cRTP, ECRTP, ROHC, etc.), this state
typically includes:
      - the values of all of the fields in all of the headers (IP,
        UDP, TCP, RTP, ICMP, ESP, etc.) that the particular header
        compression protocol operates on for the last packet of the
        flow sent (by the compressor) or received (by the
        decompressor).
      - the change in the value of some of the fields in the IP, UDP,
        TCP, etc. headers between the last two consecutive sent
        packets (compressor) or received packets (decompressor) of
        the flow. Some of the fields in the header change by a
        constant amount between subsequent packets in the flow most
        of the time. Saving the changes in these fields from packet
        to packet allows verification that a constant rate of change
        is taking place, and to take appropriate action when a
        deviation from the normal changes are encountered.
   For most HC protocols, a copy of the context of each compressed flow
   is maintained at both the compressor and the decompressor.

Context ID (CID): a small number, typically 8 bits or 16 bits, used
to identify a particular flow, and the context associated with the
flow. Most HC protocols in essence work by sending the CID across
the link in place of the full header, along with any unexpected
changes in the values in the various fields of the headers.

Forwarding Equivalence Class (FEC): a group of packets that are
forwarded in the same manner (e.g., over the same LSP, with the same
forwarding treatment)

Header Compression scheme (HC scheme): a particular method of
performing HC and its associated protocol. Multiple methods of HC
have been defined, including Robust Header Compression (ROHC
[RFC3095]), compressed RTP (cRTP, [RFC2508]), enhanced cRTP (ECRTP,
[RFC3545]), and IP Header Compression (IPHC, [RFC2507]). This draft

explicitly supports all of the HC schemes listed above, and is
intended to be extensible to others that may be developed.

Header Compression channel (HC channel): A session established
between a header compressor and a header decompressor using a single
HC scheme, over which multiple individual flows may be compressed.
From this perspective, every PPP link over which HC is operating
defines a single HC channel, and based on this specification, every
HC PW defines a single HC channel. An HC channel should not be
confused with the individual traffic flows that may be compressed
using a single Context ID. Each HC channel manages a set of unique
CIDs.

Label: a short fixed length physically contiguous identifier which is
used to identify a FEC, usually of local significance

Label Switched Path (LSP): the path through one or more LSRs at one
level of the hierarchy followed by a packet in a particular
forwarding equivalence class (FEC)

Label Switching Router (LSR): an MPLS node which is capable of
forwarding native L3 packets label stack an ordered set of labels

MPLS domain: a contiguous set of nodes which operate MPLS routing
and forwarding and which are also in one Routing or Administrative
Domain

MPLS label: a label which is carried in a packet header, and which
represents the packet's FEC

MPLS node: a node that is running MPLS. An MPLS node will be aware
of MPLS control protocols, will operate one or more L3 routing
protocols, and will be capable of forwarding packets based on labels.
An MPLS node may optionally be also capable of forwarding native L3
packets.

Multi Protocol Label Switching (MPLS): an IETF working group and the
effort associated with the working group

Packet Switched Network (PSN): Within the context of PWE3, this is a
network using IP or MPLS as the mechanism for packet forwarding.

Protocol Data Unit (PDU): The unit of data output to, or received
from, the network by a protocol layer.

Pseudowire (PW): A mechanism that carries the essential elements of
an emulated service from one provider edge router to one or more
other provider edge routers over a PSN

Pseudowire Emulation Edge to Edge (PWE3): A mechanism that emulates
the essential attributes of service (such as a T1 leased line or
Frame Relay) over a PSN

Pseudowire PDU (PW-PDU): A PDU sent on the PW that contains all of

the data and control information necessary to emulate the desired
service

PSN Tunnel: A tunnel across a PSN, inside which one or more PWs can
be carried

PSN Tunnel Signaling: Used to set up, maintain, and tear down the
underlying PSN tunnel

PW Demultiplexer: Data-plane method of identifying a PW terminating
at a provider edge router

Tunnel: A method of transparently carrying information over a network

3. Header Compression over MPLS Protocol Overview

To implement HC over MPLS, after the ingress router applies the HC
algorithm to the IP packet, the compressed packet is forwarded on an
MPLS LSP using MPLS labels, and then the egress router restores the
uncompressed header. Any of a number of HC algorithms/protocols can
be used. These algorithms have generally been designed for operation
over a single point-to-point link-layer hop. MPLS PWs [RFC3985],
which are used to provide emulation of many point-to-point link layer
services, such frame relay PVCs and ATM PVCs, are used here to
provide emulation of a single, point-to-point link layer hop over
which HC traffic may be transported.

Figure 1 illustrates an HC over MPLS channel established on an LSP
that traverses several LSRs, from R1/HC --> R2 --> R3 --> R4/HD,
where R1/HC is the ingress router performing HC, and R4/HD is the
egress router performing header decompression (HD). This example
assumes that the packet flow being compressed has RTP/UDP/IP headers
and is using a HC scheme such as ROHC, cRTP or ECRTP. Compression
of the RTP/UDP/IP header is performed at R1/HC, and the compressed
packets are routed using MPLS labels from R1/HC to R2, to R3, and
finally to R4/HD, without further decompression/recompression
cycles. The RTP/UDP/IP header is decompressed at R4/HD and can be
forwarded to other routers, as needed. This example assumes that
the application is VoIP and that the HC algorithm operates on the
RTP, UDP and IP headers of the VoIP flows. This is an extremely
common application of HC, but need not be the only one. The HC
algorithms supported by the protocol extensions specified in this
document may operate on TCP, ICMP or IPSEC ESP headers as well.

    Figure 1. Example of HC over MPLS over Routers R1 --> R4

   In the example scenario, HC therefore takes place between R1 and R4,
   and the MPLS LSP transports data/compressed-header/MPLS-labels
   instead of data/RTP/UDP/IP/MPLS-labels, saving 36 octets per packet
   in the /RTP/UDP/IP/ header. Typically there are two MPLS labels
   (8 octets) and a link-layer PW control word (2 octets). The MPLS
   label stack and link-layer headers are not compressed. Therefore HC
   over MPLS can significantly reduce the header overhead through
   compression mechanisms.

   HC reduces the IP/UDP/RTP headers to 2-4 bytes for most packets.
   Half of the reduction in header size comes from the observation that
   half of the bytes in the IP/UDP/RTP headers remain constant over the
   life of the flow. After sending the uncompressed header template
   once, these fields may be removed from the compressed headers that

follow. The remaining compression comes from the observation that
although several fields change in every packet, the difference from
packet to packet is often constant and therefore the second-order

difference is zero.

The compressor and decompressor both maintain a context for each
compressed flow. The context is the session state shared between the
compressor and decompressor. The details of what is included in the
context may vary between HC schemes. The context at the compressor
would typically include the uncompressed headers of the last packet
sent on the flow, and some measure of the differences in selected
header field values between the last packet transmitted and the
packet(s) transmitted just before it. The context atrthe
decompressor would include similar information about received
packets. With this information, all that must be communicated across
the wire is an indication of which flow a packet is associated with
(the CID), and some compact encoding of the second order differences
(i.e. the harder to predict differences) between packets.

MPLS PWs [RFC3985] are used to transport the HC packets between the
ingress and egress MPLS LSRs. Each PW acts like a logical
point-to-point link between the compressor and the decompressor.
Each PW supports a single HC channel, which, from the perspective of
the HC scheme operation, is similar to a single PPP link or a single
frame relay PVC. One exception to this general model is that PWs
carry only packets with compressed headers, and do not share the PW
with uncompressed packets.

The PW architecture specifies the use of a label stack with at least
2 levels. The label at the bottom of the stack is called the PW
label. The PW label acts as an identifier for a particular PW. With
HC PWs, the compressor adds the label at the bottom of the stack and
the decompressor removes this label. No LSRs between the compressor
and decompressor inspect or modify this label. Labels higher in the
stack are called the packet switch network (PSN) labels, and are used
to forward the packet through the MPLS network as described in
[RFC3031]. The decompressor uses the incoming MPLS PW label (the
label at the bottom of the stack), along with the CID to locate the
proper decompression context. Standard HC methods (e.g., ECRTP,
ROHC, etc.) are used to determine the contexts. The CIDs are
assigned by the HC as normal, and there would be no problem if
duplicate CIDs are received at the HD for different PWs, which
support different compressed channels. For example, if two different
compressors, HCa and HCb, both assign the same CID to each of 2
separate flows destined to decompressor HDc, HDc can still
differentiate the flows and locate the proper decompression context
for each, because the tuples <PWlabel-HCa, CID> and <PWlabel-HCb,
CID> are still unique.

In addition to the PW label and PSN label(s), HC over MPLS packets
also carry a PW control word. The control word contains both a

packet type field and a packet length field. The packet type field
is needed because each HC scheme supported by this specification
defines multiple packet types, for example "full header" packets,

which are used to initialize and/or re-synchronize the context
between compressor and decompressor, vs. normal HC packets. And most
of the HC schemes require that the underlying link layer protocols
provide the differentiation between packet types. Similarly, one of
the assumptions that is part of most of the HC schemes is that the
packet length fields in the RTP/UDP/IP, etc. headers need not be
explicitly sent across the network, because the IP datagram length
can be implicitly determined from the lower layers. This
specification assumes that, with one exception, the length of an HC
IP datagram can be determined from the link layers of the packets
transmitted across the MPLS network. The exception is for packets
that traverse an Ethernet link. Ethernet requires padding for
packets whose payload size is less than 46 bytes in length. So the
PW control word contains a length field of 6 bits to encode the
lengths of any HC packets less than 64 bytes in length.

HC PWs are set up by the PW signaling protocol [PW-SIG]. [PW-SIG]
actually defines a set of extensions to the MPLS label distribution
protocol (LDP) [RFC3036]. As defined in [PW-SIG], LDP signaling to
set up, tear down and manage PWs is performed directly between the PW
endpoints, in this case, the compressor and the decompressor. PW
signaling is used only to set up the PW label at the bottom of the
stack, and is used independently of any other signaling which may be
used to set up PSN labels. So, for example, in Figure 1, LDP PW
signaling would be performed directly between R1/HC and R4/HD.
Router R2 and R3 would not participate in PW signaling.

[PW-SIG] provides extensions to LDP for PWs, and this document
provides further extensions specific to HC. Since PWs provide a
logical point-to-point connection over which HC can be run, the
extensions specified in this document re-use elements of the
protocols used to negotiate HC over the Point-to-Point Protocol
[RFC1331]. [RFC3241] specifies how ROHC is used over PPP and
[RFC3544] specifies how several other HC schemes (cRTP, ECRTP, IPHC)
are used over PPP. Both of these RFCs provide configuration options
for negotiating HC over PPP. The formats of these configuration
options are re-used here for setting up HC over PWs. When used in
the PPP environment, these configuration options are used as
extensions to PPP's IP Control Protocol [RFC1332] and the detailed
PPP options negotiations process described in [RFC1331]. This is
necessary because a PPP link may support multiple protocols, each
with its own addressing scheme and options. Achieving
interoperability requires a negotiation process so that the nodes at
each end of the link can agree on a set of protocols and options that
both support. However, a single HC PW supports only HC traffic using
a single HC scheme. So while the formats of configuration options
from [RFC3241] and [RFC3544] are re-used here, the detailed PPP
negotiation process is not. Instead, these options are re-used here

just as descriptors (TLVs in the specific terminology of LDP and
[PW-SIG]) of basic parameters of an HC PW. These parameters are
further described in Section 4. The HC configuration parameters are

initially generated by the decompressor and describe what the
decompressor is prepared to receive.

Most HC schemes use a feedback mechanism which requires
bi-directional flow of HC packets, even if the flow of compressed
IP packets is in one direction only. The basic signaling process of
[PW-SIG] sets up unidirectional PWs, and must be repeated in each
direction in order to set up the bi-directional flow needed for HC.

Figure 1 illustrates an example data flow set up from R1/HC -->
R2 --> R3 --> R4/HD, where R1/HC is the ingress router where header
compression is performed, and R4/HD is the egress router where header
decompression is done. Each router functions as an LSR and supports
signaling of LSP/PWs. A summary of the procedures is as follows:

1. R4 initiates signaling using [PW-SIG] to create the R1 --> R4
LSP/PW that follows the path R1 --> R2 --> R3 --> R4. Depending on
the HC scheme that R4 chooses, it includes the compression parameters
taken from [RFC3241] or [RFC3544] to specify in detail what it is
prepared to receive.
2. R1 initiates signaling using [PW-SIG] to create the R4 --> R1
LSP/PW that follows the path R4 --> R3 --> R2 --> R1. It may
optionally include compression parameters taken from [RFC3241] or
[RFC3544] if the flow of compressed packets will be bi-directional.
Otherwise, the PW set up in this direction will be used only for
compression feedback.
3. R1/HC assigns a CID to the flow and uses the R1 --> R4 LSP/PW to
send HC scheme control packets and compressed packets to R4/HC, with
LSP and PW labels.
4. R4/HD uses the incoming MPLS PW label and CID to locate the proper
decompression context to decompress the compressed packets sent by
R1/HC.
5. R4/HC assigns a CID to the flow and uses the R4 --> R1 LSP/PW to
send HC scheme control packets and compressed packets to R1/HD, with
LSP and PW labels.
6. R1/HD uses the incoming MPLS PW label and CID to locate the proper
decompression context to decompress the compressed packets sent by
R4/HC.
7. if needed to resync, R4/HD sends an appropriate HC scheme control
packet to R1/HC; R1/HC responds with the appropriate HC scheme
control packet to R4/HD.
8. if needed to resync, R1/HD sends an appropriate HC scheme control
packet to R4/HC; R4/HC responds with the HC scheme control packet to
R1/HD.
9. Existing HC scheme procedures are used to assign and free up the
CIDs; see, for example, Section 7 in [ROHC-IMPL-GUIDE].

4. Protocol Specifications

Figure 2 illustrates the PW stack reference model to support PW
emulated services.

```

    |    MPLS     |<=============================>|    MPLS     |
    +-------------+                              +-------------+
    |  Physical   |                              |  Physical   |
    +-----+-------+                              +-----+-------+
```
                Figure 2: Pseudowire Protocol Stack Reference Model

Each HC-HD compressed channel MUST be identified by the PW label. A
single PW label MUST be used for many HC flows (could be 100's or
1000's) rather than assigning a different PW label to each flow. The
latter approach would involve a complex mechanism for PW label
assignment, freeing up of labels after a flow terminates, etc., for
potentially 1000's of simultaneous HC flows. On the other hand, the
mechanism for CID assignment, freeing up, etc. is in place and there
is no need to duplicate it with PW assignment/deassignment for
individual HC flows.

Multiple PWs SHOULD be established in case different QoS requirements
are needed for different compressed streams. The QoS received by the
flow would be determined by the EXP bit marking in the PW label.
Normally, all RTP packets would get the same EXP marking, equivalent
to EF treatment in DiffServ. However, the protocol specified in this
document applies to several different types of streams, not just RTP
streams, and QoS treatment other than EF may be required for those
streams.

Figure 3 shows the HC over MPLS protocol stack (with uncompressed
header):

Media stream

```
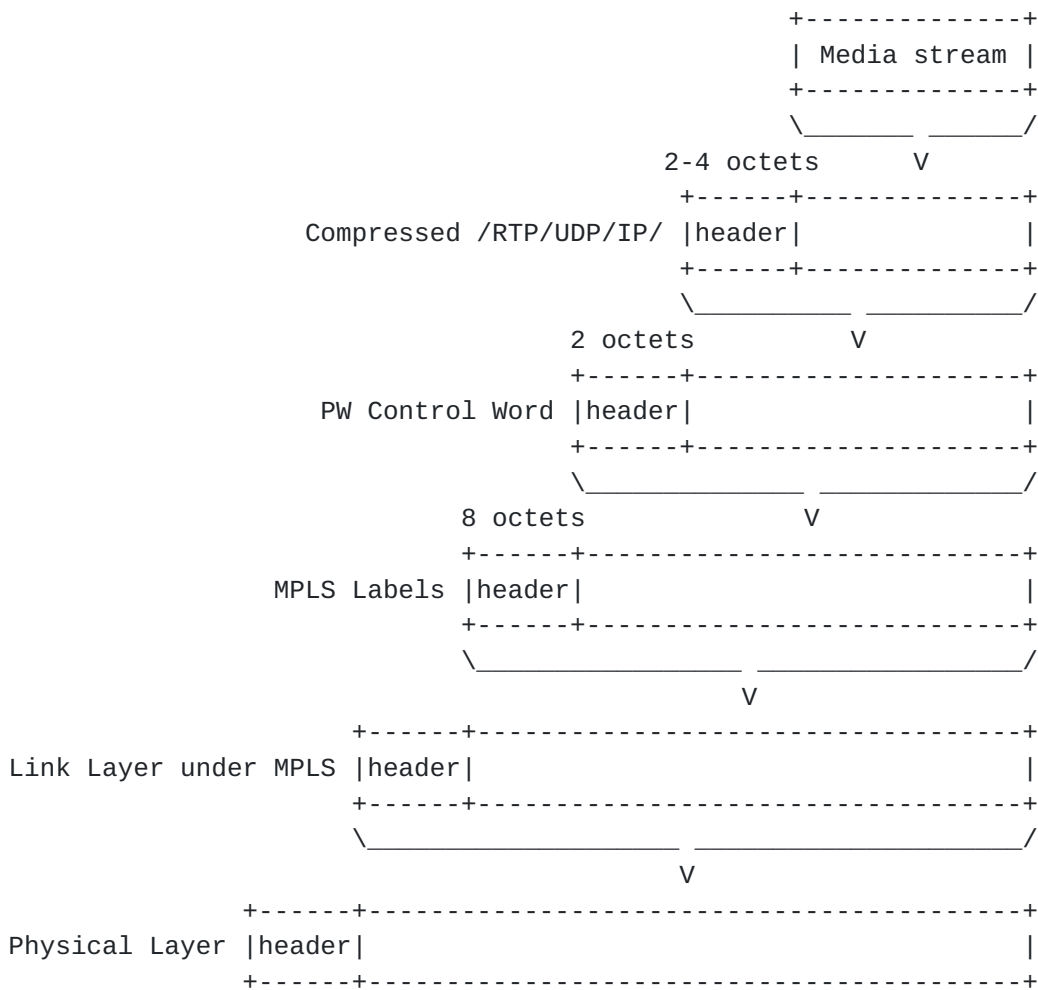

Figure 3 - Header Compression over MPLS Media Stream Transport

The PW control word MUST be to used to identify the packet types for
the HC scheme in use. The MPLS labels technically define two layers:
the PW identifier and the MPLS tunnel identifier. The PW label MUST
be used as the demultiplexer field by the HD, where the PW label
appears at the bottom label of an MPLS label stack. There can also
be other MPLS labels, for example, to identify an MPLS VPN. The
IP/UDP/RTP headers are compressed before transmission, leaving the
rest of the stack alone, as shown in Figure 3.

4.1 MPLS Pseudowire Setup & Signaling

PWs MUST be set up in advance for the transport of media streams
using [PW-SIG] control messages exchanged by the HC-HD endpoints.
Furthermore, a PW type MUST be used to indicate the HC scheme being
used on the PW. [PW-SIG] specifies the MPLS label distribution
protocol (LDP) [RFC3036] extensions to set up and maintain the PWs,
and defines new LDP objects to identify and signal attributes of PWs.

Any acceptable method of MPLS label distribution MAY be used for
distributing the MPLS tunnel label. To assign and distribute the PW
labels, an LDP session MUST be set up between the PW endpoints using

the extended discovery mechanism described in [RFC3036]. The PW
label bindings are distributed using the LDP downstream unsolicited
mode described in [RFC3036]. An LDP label mapping message contains
a forward equivalence class (FEC) object, a label object, and
possible other optional objects. The FEC object indicates the
meaning of the label, identifies the PW type, and identifies the PW
that the PW label is bound to. See [PW-SIG] for further explanation
of PW signaling.

This specification defines new PW type values to be carried within
the FEC object to identify HC PWs for each HC scheme. The PW type is
a 15-bit parameter assigned by IANA, as specified in the [IANA]
registry, and MUST be used to indicate the HC scheme being used on
the PW. The following PW type values have been reserved [IANA]:

```
0x001A  ROHC Transport Header-compressed Packets    [RFC3095]
0x001B  ECRTP Transport Header-compressed Packets   [RFC3545]
0x001C  IPHC Transport Header-compressed Packets    [RFC2507]
0x001D  cRTP Transport Header-compressed Packets    [RFC2508]
```

The PW control word enables distinguishing between various packets
types (e.g., uncompressed, UDP compressed, RTP compressed,
context-state, etc.). However, the PW control word indications are
not unique across HC schemes, and therefore the PW type value allows
the HC scheme to be identified.

4.2 Header Compression Scheme Setup, Negotiation, & Signaling

As described in the previous section, the HC PW MUST be used for
compressed packets only, which is configured at PW setup. If a flow
is not compressed, it MUST NOT be placed on the HC PW. HC PWs MUST
be bi-directional, which means that a unidirectional leg of the PW
MUST be set up in each direction. One leg of the bi-directional PW
MAY be set up to carry only compression feedback, not header
compressed traffic. The same PW type MUST be used for PW signaling
in both directions.

HC scheme parameters MAY be manually configured, but if so, manual
configuration MUST be done in both directions. If HC scheme
parameters are signaled, the Interface Parameters Sub-TLV MUST be
used on any unidirectional legs of a PW that will carry HC traffic.
For a unidirectional leg of a PW that will carry only compression
feedback, the components of the Interface Parameters Sub-TLV
described below are not relevant and MUST NOT be used.

The PW HC approach relies on the PW/MPLS layer to convey HC channel
configuration information. The Interface Parameters Sub-TLV [IANA,
PW-SIG] MUST be used to signal HC channel setup and specify HC

parameters. That is, the configuration options specified in
   [RFC3241, RFC3544] are reused in this specification to specify PW
   specific parameters, and to configure the HC and HD ports at the

edges of the PW, so that they have the necessary capabilities to
interoperate with each other.

Pseudowire Interface Parameter Sub-TLV type values are specified in
[IANA]. Two code-points have been reserved, as follows:

Parameter ID Length   Description   References
0x0D   up to 256 bytes ROHC over MPLS configuration   RFC 3241
0x0F   up to 256 bytes CRTP/ECRTP/IPHC HC over MPLS   RFC 3544
                            configuration

TLVs identified in [RFC3241] and [RFC3544] MUST be encapsulated in
the PW Interface Parameters Sub-TLV and used to negotiate header
compression session setup and parameter negotiation for their
respective protocols. The TLVs supported in this manner MUST include
the following:

o Configuration Option Format, RTP-Compression Suboption, Enhanced
  RTP-Compression Suboption, TCP/non-TCP Compression Suboptions, as
  specified in [RFC3544]
o Configuration Option Format, PROFILES Suboption, as specified in
  [RFC3241]

These TLVs are now specified in the following sections.

4.2.1 Configuration Option Format [RFC3544]

Both the network control protocol for IPv4, IPCP [RFC1332] and the
IPv6 NCP, IPV6CP [RFC2472] may be used to negotiate IP HC parameters
for their respective protocols. The format of the configuration
option is the same for both IPCP and IPV6CP. This configuration
option MUST be included for ECRTP, CRTP and IPHC PW types and MUST
NOT be included for ROHC PW types.

Description

   This NCP configuration option is used to negotiate parameters for
   IP HC. Successful negotiation of parameters enables the use of
   Protocol Identifiers FULL_HEADER, COMPRESSED_TCP,
   COMPRESSED_TCP_NODELTA, COMPRESSED_NON_TCP and CONTEXT_STATE as
   specified in [RFC2507]. The option format is summarized below.
   The fields are transmitted from left to right.

```
     0                   1                   2                   3
     0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
    |      Type      |     Length    |    IP-Compression-Protocol   |
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
    |            TCP_SPACE           |          NON_TCP_SPACE        |
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
    |           F_MAX_PERIOD         |           F_MAX_TIME          |
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
    |           MAX_HEADER           |          suboptions...       |
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

Type
   2

Length
   >= 14

The length may be increased if the presence of additional
parameters is indicated by additional suboptions.

IP-Compression-Protocol
   0061 (hex)

TCP_SPACE
   The TCP_SPACE field is two octets and indicates the maximum value
   of a context identifier in the space of context identifiers
   allocated for TCP.

      Suggested value: 15

   TCP_SPACE must be at least 0 and at most 255 (the value 0 implies
   having one context).   This field is not used for cRTP (PW type
   0x001B) and ECRTP (PW type 0x001B) PWs. For these PW types, It
   should be set to its suggested value by the sender and ignored by
   the receiver.

NON_TCP_SPACE
   The NON_TCP_SPACE field is two octets and indicates the maximum
   value of a context identifier in the space of context identifiers
   allocated for non-TCP. These context identifiers are carried in
   COMPRESSED_NON_TCP, COMPRESSED_UDP and COMPRESSED_RTP packet
   headers.

      Suggested value: 15

   NON_TCP_SPACE must be at least 0 and at most 65535 (the value 0
   implies having one context).

F_MAX_PERIOD
     Maximum interval between full headers. No more than F_MAX_PERIOD

COMPRESSED_NON_TCP headers may be sent between FULL_HEADER
headers.

Suggested value: 256

A value of zero implies infinity, i.e. there is no limit to the
number of consecutive COMPRESSED_NON_TCP headers. This field is
not used for cRTP (PW type 0x001B) and ECRTP (PW type 0x001B) PWs.
For these PW types, It should be set to its suggested value by the
sender and ignored by the receiver.

F_MAX_TIME
    Maximum time interval between full headers. COMPRESSED_NON_TCP
    headers may not be sent more than F_MAX_TIME seconds after sending
    the last FULL_HEADER header.

Suggested value: 5 seconds

A value of zero implies infinity. This field is not used for
cRTP (PW type 0x001B) and ECRTP (PW type 0x001B) PWs. For these
PW types, It should be set to its suggested value by the sender
and ignored by the receiver.

MAX_HEADER
    The largest header size in octets that may be compressed.

Suggested value: 168 octets

The value of MAX_HEADER should be large enough so that at least
the outer network layer header can be compressed. To increase
compression efficiency MAX_HEADER should be set to a value large
enough to cover common combinations of network and transport layer
headers.

suboptions
    The suboptions field consists of zero or more suboptions. Each
    suboption consists of a type field, a length field and zero or
    more parameter octets, as defined by the suboption type. The
    value of the length field indicates the length of the suboption in
    its entirety, including the lengths of the type and length fields.

```
 0                   1                   2
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|     Type      |    Length     |  Parameters...|
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

4.2.2 **RTP-Compression Suboption [RFC3544]**

The RTP-Compression suboption is included in the NCP IP-Compression-
Protocol option for IPHC if IP/UDP/RTP compression is to be enabled.

   This suboption MUST be included for cRTP PWs (0x001C) and MUST NOT be
   included for other PW types.

   Inclusion of the RTP-Compression suboption enables use of additional
   Protocol Identifiers COMPRESSED_RTP and COMPRESSED_UDP along with
   additional forms of CONTEXT_STATE as specified in [RFC2508].

   Description

      Enable use of Protocol Identifiers COMPRESSED_RTP, COMPRESSED_UDP
      and CONTEXT_STATE as specified in [RFC2508].

```
         0                   1
          0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5
         +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
         |      Type       |     Length      |
         +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

      Type
         1

      Length
         2

4.2.3 Enhanced RTP-Compression Suboption [RFC3544]

   To use the enhanced RTP HC defined in [RFC3545], a
   new sub-option 2 is added. Sub-option 2 is negotiated instead of,
   not in addition to, sub-option 1. This suboption MUST be included
   for ECRTP PWs (0x001B) and MUST NOT be included for other PW types.

   Description

      Enable use of Protocol Identifiers COMPRESSED_RTP and
      CONTEXT_STATE as specified in [RFC2508]. In addition, enable use
      of [RFC3545] compliant compression including the use of Protocol
      Identifier COMPRESSED_UDP with additional flags and use of the C
      flag with the FULL_HEADER Protocol Identifier to indicate use of
      HDRCKSUM with COMPRESSED_RTP and COMPRESSED_UDP packets.

```
         0                   1
          0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5
         +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
         |      Type       |     Length      |
         +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

      Type
         2

```
     Length
       2
```

4.2.4 Negotiating header compression for only TCP or only non-TCP Packets [RFC3544]

In RFC 2509 it was not possible to negotiate only TCP HC or only non-TCP HC because a value of 0 in the TCP_SPACE or the NON_TCP_SPACE fields actually means that 1 context is negotiated.

A new suboption 3 is added to allow specifying that the number of contexts for TCP_SPACE or NON_TCP_SPACE is zero, disabling use of the corresponding compression. This suboption MUST be included for IPHC PWs (0x001C) and MUST NOT be included for other PW types.

Description

Enable HC for only TCP or only non-TCP packets.

```
     0                   1                   2
     0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
    |     Type      |    Length     |   Parameter   |
    +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

Type

   3

Length

   3

Parameter

The parameter is 1 byte with one of the following values:

1 = the number of contexts for TCP_SPACE is 0
2 = the number of contexts for NON_TCP_SPACE is 0

This suboption overrides the values that were previously assigned to TCP_SPACE and NON_TCP_SPACE in the IP HC option.

If suboption 3 is included multiple times with parameter 1 and 2, compression is disabled for all packets.

4.2.5 Configuration Option Format [RFC3241]

Both the network control protocol for IPv4, IPCP [RFC1332] and the IPv6 NCP, IPV6CP [RFC2472] may be used to negotiate IP HC parameters for their respective protocols. The format of the configuration option is the same for both IPCP and IPV6CP. This configuration option MUST be included for ROHC PW types and MUST NOT be included

for ECRTP, CRTP and IPHC PW types.

Description

   This NCP configuration option is used to negotiate parameters for
   ROHC. The option format is summarized below.
   The fields are transmitted from left to right.

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|     Type      |    Length     |    IP-Compression-Protocol    |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|           MAX_CID             |            MRRU               |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|          MAX_HEADER           |         suboptions...
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```
Type
   2

Length
   >= 10

   The length may be increased if the presence of additional
   parameters is indicated by additional suboptions.

IP-Compression-Protocol
   0003 (hex)

MAX_CID
   The MAX_CID field is two octets and indicates the maximum value of
   a context identifier.

      Suggested value: 15

   MAX_CID must be at least 0 and at most 16383 (The value 0 implies
   having one context).

MRRU
   The MRRU field is two octets and indicates the maximum
   reconstructed reception unit (see [RFC3095], section 5.1.1).

      Suggested value: 0

MAX_HEADER
   The largest header size in octets that may be compressed.

      Suggested value: 168 octets

   The value of MAX_HEADER should be large enough so that at least

the outer network layer header can be compressed. To increase
compression efficiency MAX_HEADER should be set to a value large

enough to cover common combinations of network and transport layer
headers.

NOTE: The four ROHC profiles defined in RFC 3095 do not provide
for a MAX_HEADER parameter. The parameter MAX_HEADER defined by
this document is therefore without consequence in these profiles.
Other profiles (e.g., ones based on RFC 2507) can make use of the
parameter by explicitly referencing it.

suboptions
   The suboptions field consists of zero or more suboptions. Each
   suboption consists of a type field, a length field and zero or
   more parameter octets, as defined by the suboption type. The
   value of the length field indicates the length of the suboption in
   its entirety, including the lengths of the type and length fields.

```
        0                   1                   2
        0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3
       +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
       |     Type      |    Length     |  Parameters...
       +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

4.2.6 PROFILES Suboption [RFC3241]

The set of profiles to be enabled is subject to negotiation. Most
initial implementations of ROHC implement profiles 0x0000 to 0x0003.
This option MUST be supplied.

Description

   Define the set of profiles supported by the decompressor.

```
        0                   1                   2
        0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3
       +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
       |     Type      |    Length     |  Profiles...  |
       +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

   Type
      1

   Length
      2n+2

   Value
      n octet-pairs in ascending order, each octet-pair specifying a
      ROHC profile supported.

HC flow identification is being done now in many ways. Since there

are multiple possible approaches to the problem, no specific method
is specified in this document.

4.3 **Encapsulation of Header Compressed Packets**

The PW control word is used to identify the packet types for IPHC
[RFC2507], cRTP [RFC2508], and ECRTP [RFC3545], as shown in Figure 4:

```
                         1
         0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5
        +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
        |0 0 0 0|Pkt Typ|  Length   |Res|
        +-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```
            Figure 4 - PW Control Word

where:

"Packet Type" encoding:
0: ROHC Small-CIDs
1: ROHC Large-CIDs
2: FULL_HEADER
3: COMPRESSED_TCP
4: COMPRESSED_TCP_NODELTA
5: COMPRESSED_NON_TCP
6: COMPRESSED_RTP_8
7: COMPRESSED_RTP_16
8: COMPRESSED_UDP_8
9: COMPRESSED_UDP_16
10: CONTEXT_STATE
11-15: TO BE ASSIGNED BY IANA (see Section 8, IANA considerations,
       for discussion of the Registry)

As discussed in [ECMP-AVOID], since this MPLS payload type is not IP,
the first nibble is set to 0000 to avoid being mistaken for IP. This
is also consistent with the encoding of the PWE3 control word
[PW-CNTL-WORD].

Note that ROHC [RFC3095] provides its own packet type within the
protocol, however the PW control word MUST still be used to avoid the
problems identified above. For ROHC, the first byte of the PW
control word is set to zero.

The PW control word length field is ONLY used for short packets
because padding may be appended by the Ethernet Data Link Layer. If
the length is >= than 64 octets, the length field MUST be set to zero
[PW-CNTL-WORD]. If the MPLS payload is less than 64 bytes, the
length field MUST be set to the length of the PW payload plus the
length of the PW control word. Note that the last 2 bits in the PW
control word are reserved.

4.4 Packet Reordering

Packet reordering for ROHC and ECRTP are discussed in [ROHC-REORDER] and [ECRTP-REORDER], which are a useful source of information. In case of lossy links and other reasons for reordering, implementation adaptations are needed to allow all the schemes to be used in this case. CRTP is viewed as having risks for a number PW environments due to misordering and loss, although commercial issues lead to its choice. In these circumstances, it must be implemented and deployed with care. IPHC should use TCP_NODELTA, ECRTP should send absolute values, ROHC should be adapted as discussed in [ROHC-REORDER], and ECRTP should be adapted as discussed in [ECRTP-REORDER]. An evaluation and simulation of ECRTP and ROHC reordering is given in [REORDER-EVAL].

5. HC Pseudowire Setup Example

This example will trace the setup of an MPLS PW supporting bi-directional ECRTP [RFC3545] traffic. The example assumes the topology shown in Figure 1. The PW will be set up between LSRs R1/HC and R4/HD. LSRs R2 and R3 have no direct involvement in the signaling for this PW, other than to transport the signaling traffic.

For this example, it is assumed that R1/HC has already obtained the IP address of R4/HD used for LDP signaling, and vice versa, that both R1/HC and R4/HD have been configured with the same 32 bit PW ID, as described in Section 5.2 of [PW-SIG], and that R1/HC has been configured to initiate the LDP discovery process. Furthermore, we assume that R1/HC has been configured to receive a maximum of 200 simultaneous ECRTP flows from R4/HD, and R4/HD has been configured to receive a maximum of 255 ECRTP flows from R1/HC.

Assuming that there is no existing LDP session between R1/HC and R4/HD, the PW signaling must start by setting up an LDP session between them. As described earlier in this document, LDP extended discovery is used between HC over MPLS LSRs. Since R1/HC has been configured to initiate extended discovery, it will send LDP Targeted Hello messages to R4/HD's IP address at UDP port 646. The Targeted Hello messages sent by R1/HC will have the "R" bit set in the Common Hello Parameters TLV, requesting R4/HD to send Targeted Hello messages back to R1/HC. Since R4/HD has been configured to set up an HC PW with R1/HD, R4/HD will do as requested and send LDP Targeted Hello messages as unicast UDP packets to UDP port 646 of R1/HC's IP address.

When R1/HC receives a Targeted Hello message from R4/HD, it may begin establishing an LDP session to R4/HD. It starts this by initiating a TCP connection on port 646 to R4/HD's signaling IP address. After

successful TCP connection establishment, R1/HC sends an LDP
Initialization message to R4/HD with the following characteristics:

    o Common Session Parameters TLV:
      - A bit = 0 (Downstream Unsolicited Mode)
      - D bit = 0 (Loop Detection Disabled)
      - PVLim = 0 (required when D bit = 0)
      - Receive LDP identifier:
        > 4 octets of R1/HC's signaling IP address
        > 2 octet Label space identifier (typically 0)
    o No Optional Parameters TLV:

    Following the LDP session initialization state machine of [Section 2.5.4 of [RFC3036]], R4/HD would send a similar Initialization message to R1/HD. The primary difference would be that R4/HD would use its own signaling IP address in the LDP identifier. Assuming that all other fields in the Common Session Parameters TLV were acceptable to both sides, R1/HC would send an LDP Keepalive message to R4/HD, R4/HD would send a LDP Keepalive message to R1/HC, and the LDP session would become operational.

    At this point, either R1/HC or R4/HD may send LDP Label Mapping messages to configure the PW. The Label Mapping message sent by a particular router advertises the label that should be used at the bottom of the MPLS label stack for all packets sent to that router and associated with the particular PW. The Label Mapping message sent from R1/HC to R4/HD would have the following characteristics:

    o FEC TLV
      - FEC Element type 0x80 (Pwid FEC Element, as defined in [PW-SIG]
      - Control Word bit = 1 (Control Word present)
      - PW type = 0x001B (ECRTP [RFC 3545])
      - Group ID as chosen by R1/HC
      - PW ID = the configured value for this PW, which must be the same
        as that sent in the Label Mapping message by R4/HD
      - Interface Parameter Sub-TLVs
        > Interface MTU sub-TLV (Type 0x01)
        > CRTP/ECRTP/IPHC HC over MPLS configuration sub-TLV (Type 0x0F)
          + Type = 2 (From RFC 3544)
          + Length = 16
          + TCP_SPACE = Don't Care (leave at suggested value = 15)
          + NON_TCP_SPACE = 200 (configured on R1)
          + F_MAX_PERIOD = Don't Care (leave at suggested value = 256)
          + F_MAX_TIME = Don't Care (leave at suggested value = 5
            seconds)
          + MAX_HEADER = 168 (Suggested Value)
          + Enhanced RTP-Compression Suboption
            & Type = 2
            & Length = 2
    o Label TLV - contains label selected by R1, Lr1
    o No Optional Parameters

The Label Mapping message sent from R4/HD to R1/HC would be almost
identical to the one sent in the opposite direction, with the

following exceptions

o R4/HD could select a different Group ID
o The Value of NON_TCP_SPACE in the CRTP/ECRTP/IPHC HC over MPLS
  configuration sub-TLV would be 255 instead of 200, as configured
  on R4/HD
o R4/HD would choose its own value for the Label TLV, Lr4

As soon as either R1/HC or R4/HD had both transmitted and received
Label Mapping Messages with the same PW Type and PW ID, it could
consider the PW established. R1/HC could send ECRTP packets using
the label it received in the Label Mapping Message from R4/HD, Lr4,
and could identify received ECRTP packets by the label it had sent to
R4/HD, Lr1. And vice versa.

In this case, assume that R1/HC has an IPv4 RTP flow to send to R4/HD
that it wishes to compress using the ECRTP PW just set up. The RTP
flow is G.729 media with 20 bytes of payload in each RTP packet. In
this particular case, the IPv4 identifier changes by a small constant
value between consecutive packets in the stream. In the RTP layer of
the flow, the Contributing Source Identifiers count is 0. R1/HC
decides to use 8-bit Context Identifiers for the compressed flow.
Also, R1/HC determines that compression in this particular flow
should be able to recover from the loss of 2 consecutive packets
without requiring re-synchronization of the context (i.e. the "N"
value from [RFC3545] is 2).

The first 3 (N + 1) packets of this flow would be sent as FULL_HEADER
packets. The MPLS and PW headers at the beginning of these packets
would be formatted as follows:

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                  Label                | Exp |S|       TTL     |
|                   XX                  |  XX |0|       XX      |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                  Label                | Exp |S|       TTL     |
|                   Lr4                 |  XX |1|       >0      |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|       |Pkt Typ|  Length    |Res|
|0 0 0 0|   2   |     62     |0 0|
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
            ^
            |
             -- 2 == FULL_HEADER

      where XX signifies either
```

a. value determined by the MPLS routing layer
            b. don't care

Immediately following the above header would come the FULL_HEADER
packet as defined in [RFC3545], which basically consists of the
IP/UDP/RTP header, with the IP and UDP length field replaced by
values encoding the CID, sequence number and "generation", as defined
in [RFC3545]. The length field value of 62 comprises:

o 2 bytes of PW control word (included in the above diagram)
o 20 bytes of the IP header portion of the RFC 3545 FULL_HEADER
o 8 bytes of the UDP header portion of the RFC 3545 FULL_HEADER
o 12 bytes of the RTP header portion of the RFC 3545 FULL_HEADER
o 20 bytes of G.729 payload

The following 3 RTP packets from this flow would be sent as
COMPRESSED_UDP_8, to establish the absolute and delta values of the
IPv4 identifier and RTP timestamp fields. These packets would use
the same ECRTP CID as the previous 3 FULL_HEADER packets. The MPLS
and PW headers at the beginning of these packets would be formatted
as follows:

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                 Label                 | Exp |S|      TTL      |
|                  XX                   |  XX |0|      XX       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                 Label                 | Exp |S|      TTL      |
|                  Lr4                  |  XX |1|      >0       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|       |Pkt Typ|  Length     |Res|
|0 0 0 0|   8   |     36      |0 0|
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
           ^
           |
            -- 8 == COMPRESSED_UDP_8
```

There is no change in the MPLS label stack between the FULL_HEADER
packets and the COMPRESSED_UDP packets. The PW control word changes
to reflect another ECRTP packet type following the control word, and
a change of packet length. The length changes because the new packet
type more compactly encodes the headers. The length field value of
36 comprises:

o 2 bytes of PW control word (included in the above diagram)
o 1 byte of CID
  - 4 bits of COMPRESSED_UDP flags
  - 4 bits of sequence number
  - 5 bits of COMPRESSED UDP extension flags

- 3 bits MUST_BE_ZERO
        o 2 bytes of UDP checksum or HDRCKSUM
        o 1 byte of delta IPv4 ID

   o 2 bytes of delta RTP timestamp (changes by 160 in this case,
      differential encoding will encode as 2 bytes)
   o 2 bytes of absolute IPv4 ID
   o 4 bytes of absolute RTP timestamp
   o 20 bytes of G.729 payload

   After the context for the IPv4 ID and RTP timestamp is initialized.
   Subsequent packets on this flow, at least until the end of the talk
   spurt or until there is some other unexpected change in the
   IP/UDP/RTP headers, may be sent as COMPRESSED_RTP_8 packets. Again,
   the same MPLS stack would be used for these packets, and the same
   value of the CID would be used in this case as for the packets
   described above. The MPLS and PW headers at the beginning of these
   packets would be formatted as follows:

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|              Label                    | Exp |S|      TTL      |
|               XX                      |  XX |0|      XX       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|              Label                    | Exp |S|      TTL      |
|               Lr4                     |  XX |1|      >0       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|       |Pkt Typ|  Length    |Res|
|0 0 0 0|   6   |     26     |0 0|
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
           ^
           |
            -- 6 == COMPRESSED_RTP_8
```

   The PW control word again changes to reflect another ECRTP packet
   type following the control word, and shorter length associated with
   an even more compact encoding of headers. The length field value of
   26 comprises:

   o 2 bytes of PW control word (included in the above diagram)
   o 1 byte of CID
     - 4 bits of COMPRESSED_RTP flags
     - 4 bits of sequence number
   o 2 bytes of UDP checksum or HDRCKSUM
   o 20 bytes of G.729 payload

   Additional flows in the same direction may be compressed using the
   same basic encapsulation, including the same PW label. The CID that
   is part of the HC protocol is used to differentiate flows. For
   traffic in the opposite direction, the primary change would be the PW
   label, Lr4, used in the example above would be replaced by the label

Lr1 that R1/HC provides to R4/HD.

6. Security Considerations

   MPLS PW security considerations in general are discussed in
   [RFC3985] and [PW-SIG], and those considerations also apply to this
   document. This document specifies an encapsulation and not the
   protocols that may be used to carry the encapsulated packets across
   the PSN, or the protocols being encapsulated. Each such protocol may
   have its own set of security issues, but those issues are not
   affected by the encapsulations specified herein.

   The security considerations of the supported HC protocols [RFC2507,
   RFC2508, RFC3095, RFC3545] all apply to this document as well.

7. Acknowledgements

   The authors appreciate valuable inputs and suggestions from Loa
   Andersson, Scott Brim, Stewart Bryant, Adrian Farrel, Victoria
   Fineberg, Allison Mankin, Luca Martini, Colin Perkins, Kristofer
   Sandlund, Yaakov Stein, George Swallow, Curtis Villamizar, and Magnus
   Westerlund.

8. IANA Considerations

   As discussed in Section 4.1, PW type values need to be assigned by
   IANA, as follows:

   0x001A ROHC Transport Header-compressed Packets   [RFC3095]
   0x001B ECRTP Transport Header-compressed Packets   [RFC3545]
   0x001C IPHC Transport Header-compressed Packets   [RFC2507]
   0x001D cRTP Transport Header-compressed Packets   [RFC2508]

   Procedures for registering new PW type values are given in [IANA].

   As discussed in Section 4.2, Pseudowire Interface Parameter Sub-TLV
   type values need to be specified by IANA, as follows:

   Parameter ID Length   Description   References
   0x0D   up to 256 bytes ROHC over MPLS configuration   RFC 3241
   0x0F   up to 256 bytes CRTP/ECRTP/IPHC HC over MPLS   RFC 3544
                              configuration

   As discussed in Section 4.3, IANA needs to define a new registry,
   "Header Compression Over MPLS PW Control Word Packet Type". This is
   a four bit value. Packet Types 0 through 10 are defined in Section
   4.3 of this document. Packet Types 11 to 15 are to be assigned by
   IANA using the "Expert Review" policy defined in [RFC2434].
