**The SEED Cipher Algorithm and Its Use with the Secure Real-time  
Transport Protocol (SRTP)  
draft-ietf-avt-seed-srtp-14**

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on December 15, 2009.

## Abstract

This document describes the use of the SEED block cipher algorithm in the Secure Real-time Transport Protocol (SRTP) for providing confidentiality for the Real-time Transport Protocol (RTP) traffic and for the control traffic for RTP, the Real-time Transport Control Protocol (RTCP).

## **1. Introduction**

This document describes the use of the SEED [[RFC4269](#)] block cipher algorithm in the Secure Real-time Transport Protocol (SRTP) [[RFC3711](#)] for providing confidentiality for the Real-time Transport Protocol (RTP) [[RFC3550](#)] traffic and for the control traffic for RTP, the Real-time Transport Control Protocol (RTCP) [[RFC3550](#)].

### **1.1. SEED**

SEED is a Korean National Industrial Association standard and is widely used in South Korea for electronic commerce and financial services that are operated on wired and wireless communications.

SEED is a 128-bit symmetric key block cipher that has been developed by KISA (Korea Information Security Agency) and a group of experts since 1998. The input/output block size of SEED is 128-bit and the key length is also 128-bit. SEED has a 16-round Feistel structure.

### **1.2. Terminology**

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

### **1.3. Definitions**

|| concatenation  
XOR exclusive or

## **2. Cryptographic Transforms**

All symmetric block cipher algorithms share common characteristics including mode, key size, weak keys, and block size. The following sections contain descriptions of the relevant characteristics of SEED.

SEED does not have any restrictions for modes of operation that are used with this block cipher. We define three modes of running SEED, (1) SEED in Counter Mode, (2) SEED in Counter with CBC-MAC (CCM) Mode and (3) SEED in Galois/Counter Mode (GCM) Mode.

### **2.1. Counter**

[Section 4.1.1 of \[RFC3711\]](#) defines AES counter mode encryption, which it refers to as AES-CM. SEED counter mode is defined in a similar manner, and is denoted as SEED-CTR. The plaintext inputs to the block cipher are formed as in AES-CM, and the block cipher outputs are processed as in AES-CM. The only difference in the processing is that SEED-CTR uses SEED as the underlying encryption primitive. When SEED-CTR is used, it **MUST** be used only in conjunction with an authentication function.

#### **2.1.1. Message Authentication/Integrity: HMAC-SHA1**

HMAC-SHA1 [[RFC2104](#)], as defined in [section 4.2.1 of \[RFC3711\]](#), SHALL be the default message authentication code to be used with SEED-CTR. The default session authentication key-length SHALL be 160 bits, the default authentication tag length SHALL be 80 bits, and the SRTP\_PREFIX\_LENGTH SHALL be zero for HMAC-SHA1. For SRTP, smaller values are NOT RECOMMENDED, but MAY be used after careful consideration of the issues in [section 7.5](#) and 9.5 of [[RFC3711](#)].

### **2.2. Counter with CBC-MAC (CCM)**

CCM is a generic authenticate-and-encrypt block cipher mode [[RFC3610](#)]. In this specification, CCM used with the SEED block cipher is denoted as SEED-CCM.

[Section 3.3 of \[RFC3711\]](#) defines procedures to construct or to authenticate and decrypt SRTP packets. For SEED-CCM however, the sender performs Step 7 before Step 5 and the receiver performs the second half of Step 5 (performs verification) after Step 6. This means that authentication is performed on the plaintext rather than the ciphertext. This applies equally to SRTCP.

All SRTP packets **MUST** be authenticated and encrypted. Unlike SRTP, SRTCP packet encryption is optional (but authentication is

mandatory). A sender can select which packets to encrypt, and indicates this choice with a 1-bit encryption flag (located in the leftmost bit of the 32-bit word that contains the SRTCP index).

SEED-CCM has two parameters:

- M M indicates the size of the authentication tag. In SRTP, a full 80-bit authentication-tag SHOULD be used and implementation of this specification MUST support M values of 10 octets.
- L L indicates the size of the length field in octets. The number of octets in the nonce MUST be 12, i.e., L is 3.

SEED-CCM has four inputs:

#### Key

A single key is used to calculate the authentication tag using CBC-MAC and to perform payload encryption using counter mode. SEED only supports a key size of 128 bits.

#### Nonce

The size of the nonce depends on the value selected for the parameter L. It is 15-L octets. L equals 3 and hence the nonce size equals 12 octets.

#### Plaintext

In case of SRTP, the payload of the RTP packet and the RTP padding and RTP pad count field (if the latter two fields are present).

In case of SRTCP, when the encryption flag is set to 1, the Encrypted Portion described in Fig.2 of [[RFC3711](#)] is treated as plaintext. When the encryption flag is set to 0, the plaintext is zero-length.

### Additional Authentication Data (AAD)

In case of SRTP, the header of the RTP packet including contributing source (CSRC) identifier (if present) and the RTP header extension (if present).

In case of SRTCP, when the encryption flag is set to 0, the Authentication Portion described in Fig.2 of [[RFC3711](#)] is treated as AAD. When the encryption flag is set to 1, the first 8-octets, the encryption flag and SRTCP index are treated as AAD.

SEED-CCM accepts these four inputs and returns a ciphertext field.

### **[2.3. Galois/Counter Mode \(GCM\)](#)**

GCM is a block cipher mode of operation providing both confidentiality and data origin authentication [[GCM](#)]. GCM used with the SEED block cipher is denoted as SEED-GCM.

SEED-GCM has four inputs: a key, a plaintext, a nonce and the additional authenticated data (AAD) all described in [section 2.2](#).

The bit length of the tag, denoted  $t$ , is 12, and an authentication tag with a length of 12 octets (96 bits) is used.

## **[3. Nonce Format for CCM and GCM](#)**

### **[3.1. Nonce for SRTP](#)**

The nonce for SRTP SHALL be formed in the following way:

$$\text{Nonce} = (16 \text{ bits of zeroes} \parallel \text{SSRC} \parallel \text{ROC} \parallel \text{SEQ}) \text{ XOR Salt}$$

The 4-octet SSRC and the 2-octet SEQ SHALL be taken from the RTP header. The 4-octet ROC is from the cryptographic context. The 12-octet Salt SHALL be produced by the SRTP Key Derivation Function.

### **[3.2. Nonce for SRTCP](#)**

The nonce for SRTCP SHALL be formed in the following way:

$$\text{Nonce} = (16 \text{ bits of zeroes} \parallel \text{SSRC} \parallel 16 \text{ bits of zeroes} \parallel \text{SRTCP index}) \text{ XOR Salt}$$

The 4-octet SSRC SHALL be taken from the RTCP header and The 31-bit SRTCP index (packed zero-filled, right justified into a 4-octet

field) is from each packet. The 12-octet Salt SHALL be produced by the SRTP Key Derivation Function.

#### 4. Key Derivation: SEED-CTR PRF

[Section 4.3.3 of \[RFC3711\]](#) defines the AES-128 counter mode key derivation function, which it refers to as "AES-CM PRF". The SEED-CTR PRF is defined in a similar manner, but with each invocation of AES replaced with an invocation of SEED.

The currently defined PRF, keyed by the 128-bit master key, has input block size  $m = 128$  and can produce  $n$ -bit outputs for  $n$  up to  $2^{23}$ .  $\text{SEED-PRF}_n(k_{\text{master}}, x)$  SHALL be SEED in Counter Mode as described in [section 2.1](#), applied to key  $k_{\text{master}}$ , and IV equal to  $(x \cdot 2^{16})$ , and with the output keystream truncated to the  $n$  first (left-most) bits.

#### 5. Mandatory-to-implement Transforms

"Mandatory-to-implement" means conformance to the specification, and that Table 1 does not supersede a similar table in [Section 5 of \[RFC3711\]](#). An RTP implementation that supports SEED MUST implement the modes listed in Table 1.

	mandatory-to-implement	optional
encryption	SEED-CTR	SEED-CCM, SEED-GCM
message integrity	HMAC-SHA1	SEED-CCM, SEED-GCM
key derivation (PRF)	SEED-CTR	-

Table 1: Mandatory-to-implement and optional transforms in SRTP and SRTCP.

#### 6. Security Considerations

No security problem has been found on SEED. SEED is secure against all known attacks including Differential cryptanalysis, linear cryptanalysis, and related key attacks. The best known attack is only an exhaustive search for the key. For further security considerations, the reader is encouraged to read [\[SEED-EVAL\]](#).

See [\[RFC3610\]](#) and [\[GCM\]](#) for security considerations regarding the CCM and GCM Modes of Operation, respectively. In the context of SRTP, the procedures in [\[RFC3711\]](#) ensure the critical property of non-reuse of counter values.

## 7. IANA Considerations

[RFC4568] defines SRTP "crypto suites". In order to allow SDP to signal the use of the algorithms defined in this document, IANA will register the following crypto suites into the subregistry for SRTP crypto suites under the SRTP transport of the SDP Security Descriptions:

```
srtp-crypto-suite-ext = "SEED_CTR_128_HMAC_SHA1_80"/  
                        "SEED_128_CCM_80"/  
                        "SEED_128_GCM_96"/  
srtp-crypto-suite-ext
```
