Methodology for Benchmarking Session Initiation Protocol (SIP) Devices:

Basic session setup and registration

draft-ietf-bmwg-sip-bench-meth-11

Abstract

This document provides a methodology for benchmarking the Session Initiation Protocol (SIP) performance of devices. Terminology related to benchmarking SIP devices is described in the companion terminology document. Using these two documents, benchmarks can be obtained and compared for different types of devices such as SIP Proxy Servers, Registrars and Session Border Controllers. The term "performance" in this context means the capacity of the device-undertest (DUT) to process SIP messages. Media streams are used only to study how they impact the signaling behavior. The intent of the two documents is to provide a normalized set of tests that will enable an objective comparison of the capacity of SIP devices. Test setup parameters and a methodology are necessary because SIP allows a wide range of configuration and operational conditions that can influence performance benchmark measurements.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of $\underline{\mathsf{BCP}}$ 78 and $\underline{\mathsf{BCP}}$ 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 3, 2015.

1. Terminology

In this document, the key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" are to be interpreted as described in BCP 14, conforming to [RFC2119] and indicate requirement levels for compliant implementations.

<u>RFC 2119</u> defines the use of these key words to help make the intent of standards track documents as clear as possible. While this document uses these keywords, this document is not a standards track document. The term Throughput is defined in [RFC2544].

Terms specific to SIP [RFC3261] performance benchmarking are defined in [I-D.sip-bench-term].

2. Introduction

This document describes the methodology for benchmarking Session Initiation Protocol (SIP) performance as described in the Terminology document [I-D.sip-bench-term]. The methodology and terminology are to be used for benchmarking signaling plane performance with varying signaling and media load. Media streams, when used, are used only to study how they impact the signaling behavior. This document concentrates on benchmarking SIP session setup and SIP registrations only.

The device-under-test (DUT) is a RFC3261 network intermediary that plays the role of a registrar, redirect server, stateful proxy, a Session Border Controller (SBC) or a B2BUA. This document does not require the intermediary to assume the role of a stateless proxy. Benchmarks can be obtained and compared for different types of devices such as a SIP proxy server, Session Border Controllers (SBC), SIP registrars and a SIP proxy server paired with a media relay.

The test cases provide metrics for benchmarking the maximum 'SIP Registration Rate' and maximum 'SIP Session Establishment Rate' that the DUT can sustain over an extended period of time without failures (extended period of time is defined in the algorithm in Section 4.10). Some cases are included to cover encrypted SIP. The test topologies that can be used are described in the Test Setup section. Topologies in which the DUT handles media as well as those in which the DUT does not handle media are both considered. The measurement of the performance characteristics of the media itself is outside the scope of these documents.

Benchmark metrics could possibly be impacted by Associated Media. The selected values for Session Duration and Media Streams per Session enable benchmark metrics to be benchmarked without Associated Media. Session Setup Rate could possibly be impacted by the selected value for Maximum Sessions Attempted. The benchmark for Session Establishment Rate is measured with a fixed value for maximum Session Attempts.

Finally, the overall value of these tests is to serve as a comparison function between multiple SIP implementations. One way to use these tests is to derive benchmarks with SIP devices from Vendor-A, derive a new set of benchmarks with similar SIP devices from Vendor-B and perform a comparison on the results of Vendor-A and Vendor-B. This document does not make any claims on the interpretation of such results.

3. Benchmarking Topologies

Test organizations need to be aware that these tests generate large volumes of data and consequently ensure that networking devices like hubs, switches or routers are able to handle the generated volume.

The test cases enumerated in <u>Section 6.1</u> to <u>Section 6.6</u> operate on two test topologies: one in which the DUT does not process the media (Figure 1) and the other in which it does process media (Figure 2). In both cases, the tester or EA sends traffic into the DUT and absorbs traffic from the DUT. The diagrams in Figure 1 and Figure 2 represent the logical flow of information and do not dictate a particular physical arrangements of the entities.

Figure 1 depicts a layout in which the DUT is an intermediary between the two interfaces of the EA. If the test case requires the exchange of media, the media does not flow through the DUT but rather passes directly between the two endpoints. Figure 2 shows the DUT as an intermediary between the two interfaces of the EA. If the test case requires the exchange of media, the media flows through the DUT between the endpoints.

Figure 1: DUT as an intermediary, end-to-end media

Figure 2: DUT as an intermediary forwarding media

The test cases enumerated in <u>Section 6.7</u> and <u>Section 6.8</u> use the topology in Figure 3 below.

Figure 3: Registration and Re-registration tests

During registration or re-registration, the DUT may involve backend network elements and data stores. These network elements and data stores are not shown in Figure 3, but it is understood that they will impact the time required for the DUT to generate a response.

This document explicitly separates a registration test (Section 6.7) from a re-registration test (Section 6.8) because in certain networks, the time to re-register may vary from the time to perform an initial registration due to the backend processing involved. It is expected that the registration tests and the re-registration test will be performed with the same set of backend network elements in order to derive a stable metric.

4. Test Setup Parameters

4.1. Selection of SIP Transport Protocol

Test cases may be performed with any transport protocol supported by SIP. This includes, but is not limited to, TCP, UDP, TLS and websockets. The protocol used for the SIP transport protocol must be reported with benchmarking results.

SIP allows a DUT to use different transports for signaling on either side of the connection to the EAs. Therefore, this document assumes that the same transport is used on both sides of the connection; if this is not the case in any of the tests, the transport on each side of the connection MUST be reported in the test reporting template.

4.2. Connection-oriented Transport Management

SIP allows a device to open one connection and send multiple requests over the same connection (responses are normally received over the same connection that the request was sent out on). The protocol also allows a device to open a new connection for each individual request. A connection management strategy will have an impact on the results obtained from the test cases, especially for connection-oriented transports such as TLS. For such transports, the cryptographic handshake must occur every time a connection is opened.

The connection management strategy, i.e., use of one connection to send all requests or closing an existing connection and opening a new connection to send each request, MUST be reported with the benchmarking result.

4.3. Signaling Server

The Signaling Server is defined in the companion terminology document, ([I-D.sip-bench-term], Section 3.2.2). The Signaling Server is a DUT.

4.4. Associated Media

Some tests require Associated Media to be present for each SIP session. The test topologies to be used when benchmarking DUT performance for Associated Media are shown in Figure 1 and Figure 2.

4.5. Selection of Associated Media Protocol

The test cases specified in this document provide SIP performance independent of the protocol used for the media stream. Any media protocol supported by SIP may be used. This includes, but is not limited to, RTP, and SRTP. The protocol used for Associated Media MUST be reported with benchmarking results.

4.6. Number of Associated Media Streams per SIP Session

Benchmarking results may vary with the number of media streams per SIP session. When benchmarking a DUT for voice, a single media stream is used. When benchmarking a DUT for voice and video, two media streams are used. The number of Associated Media Streams MUST be reported with benchmarking results.

4.7. Codec Type

The test cases specified in this document provide SIP performance independent of the media stream codec. Any codec supported by the EAs may be used. The codec used for Associated Media MUST be reported with the benchmarking results.

4.8. Session Duration

The value of the DUT's performance benchmarks may vary with the duration of SIP sessions. Session Duration MUST be reported with benchmarking results. A Session Duration of zero seconds indicates transmission of a BYE immediately following a successful SIP establishment. Setting this parameter to the value '0' indicates that a BYE will be sent by the EA immediately after the EA receives a 200 OK to the INVITE. Setting this parameter to a time value greater than the duration of the test indicates that a BYE is never sent.

4.9. Attempted Sessions per Second (sps)

The value of the DUT's performance benchmarks may vary with the Session Attempt Rate offered by the tester. Session Attempt Rate MUST be reported with the benchmarking results.

The test cases enumerated in <u>Section 6.1</u> to <u>Section 6.6</u> require that the EA is configured to send the final 2xx-class response as quickly as it can. This document does not require the tester to add any delay between receiving a request and generating a final response.

4.10. Benchmarking algorithm

In order to benchmark the test cases uniformly in <u>Section 6</u>, the algorithm described in this section should be used. A prosaic description of the algorithm and a pseudo-code description are provided below, and a simulation written in the R statistical language [Rtool] is provided in <u>Appendix A</u>.

The goal is to find the largest value, R, a SIP Session Attempt Rate, measured in sessions-per-second (sps), which the DUT can process with zero errors over a defined, extended period. This period is defined as the amount of time needed to attempt N SIP sessions, where N is a parameter of test, at the attempt rate, R. An iterative process is used to find this rate. The algorithm corresponding to this process converges to R.

If the DUT vendor provides a value for R, the tester can use this value. Alternatively, in cases where the DUT vendor does not provide a value for R, or in cases where the tester wants to ascertain a vendor provided value using local media characteristics, the algorithm could be run by setting "r = R" and observing the value at convergence.

The algorithm proceeds by initializing "r = 100"; "r" is the session attempt rate. The algorithm dynamically increases and decreases "r" as it converges to the a maximum sps value for R. The dynamic increase and decrease rate is controlled by the weights "w" and "d", respectively. If the DUT vendor provides a value for R, the tester can use that value; however, because the requirements and media characteristics are a function of the test environment, it is best that the tester reflect these requirements during testing and allow the algorithm to converge to R.

The pseudo-code corresponding to the description above follows, and a simulation written in the R statistical language is provided in Appendix A.

```
; ---- Parameters of test, adjust as needed
N := 50000 ; Global maximum; once largest session rate has
            ; been established, send this many requests before
            ; calling the test a success
m := {\ldots}; Other attributes that affect testing, such
            ; as media streams, etc.
            ; Initial session attempt rate (in sessions/sec).
r := 100
             ; Adjust as needed (for example, if DUT can handle
            ; thousands of calls in steady state, set to
            ; appropriate value in the thousands).
w := 0.10; Traffic increase weight (0 < w <= 1.0)
d := max(0.10, w / 2); Traffic decrease weight
; ---- End of parameters of test
proc find_R
  R = \max_{s} (r, m, N); Setup r sps, each with m media
   ; characteristics until N sessions have been set up.
   ; Note that if a DUT vendor provides this number, the tester
   ; can use the number as a Session Attempt Rate, R, instead
   ; of invoking max_sps()
end proc
; Iterative process to figure out the largest number of
; sps that we can achieve in order to setup n sessions.
; This function converges to R, the Session Attempt Rate.
proc max_sps(r, m, n)
       := 0 ; session setup rate
   old_r := 0 ; old session setup rate
       := 0 ; Return value, R
  count := 0
   ; Note that if w is small (say, 0.10) and r is small
   ; (say, <= 9), the algorithm will not converge since it
   ; uses floor() to increment r dynamically. It is best
   ; off to start with the defaults (w = 0.10 and
   ; r >= 10)
  while (TRUE) {
     s := send_traffic(r, m, n) ; Send r sps, with m media
      ; characteristics until n sessions established.
     if (s == n) {
         if (r > old_r) {
             old_r = r
         }
         else {
```

```
count = count + 1
             if (count >= 10) {
                 # We've converged.
                 h := max(r, old_r)
                 break
            }
         }
         r := floor(r + (w * r))
     }
     else {
         r := floor(r - (d * r))
         d := max(0.10, d / 2)
         W := max(0.10, W / 2)
     }
  }
  return h
end proc
```

Reporting Format

<u>5.1</u>. Test Setup Report

<pre>SIP Transport Protocol = (valid values: TCP UDP TLS SCTP websockets specify-other) (specify if same transport used for connections to the DUT and connections from the DUT. If different transports used on each connection, enumerate the transports used) Connection management strategy for connection oriented transports DUT receives requests on one connection = (yes or no. If no, DUT accepts a new connection for every incoming request, sends a response on that connection and closes the connection) DUT sends requests on one connection = (yes or no. If no, DUT initiates a new connection to send out each request, gets a response on that connection and closes the connection)</pre>
Session Attempt Rate = (session attempts/sec)
Total Sessions Attempted =(total sessions to be created over duration of test)
Media Streams Per Session = (number of streams per session)

other parameters that may impact the rate)

6. Test Cases

6.1. Baseline Session Establishment Rate of the test bed

Objective:

To benchmark the Session Establishment Rate of the Emulated Agent (EA) with zero failures.

Procedure:

- 1. Configure the DUT in the test topology shown in Figure 1.
- 2. Set media streams per session to 0.
- 3. Execute benchmarking algorithm as defined in Section 4.10 to get the baseline session establishment rate. This rate MUST be recorded using any pertinent parameters as shown in the reporting format of <u>Section 5.1</u>.

Expected Results: This is the scenario to obtain the maximum Session Establishment Rate of the EA and the test bed when no DUT is present. The results of this test might be used to normalize test results performed on different test beds or simply to better understand the impact of the DUT on the test bed in question.

6.2. Session Establishment Rate without media

Objective:

To benchmark the Session Establishment Rate of the DUT with no associated media and zero failures.

Procedure:

- 1. Configure a DUT according to the test topology shown in Figure 1 or Figure 2.
- 2. Set media streams per session to 0.
- 3. Execute benchmarking algorithm as defined in Section 4.10 to get the session establishment rate. This rate MUST be recorded using any pertinent parameters as shown in the reporting format of <u>Section 5.1</u>.

Expected Results: Find the Session Establishment Rate of the DUT when the EA is not sending media streams.

6.3. Session Establishment Rate with Media not on DUT

Objective:

To benchmark the Session Establishment Rate of the DUT with zero failures when Associated Media is included in the benchmark test but the media is not running through the DUT.

Procedure:

- 1. Configure a DUT according to the test topology shown in Figure 1.
- 2. Set media streams per session to 1.
- 3. Execute benchmarking algorithm as defined in Section 4.10 to get the session establishment rate with media. This rate MUST be recorded using any pertinent parameters as shown in the reporting format of Section 5.1.

Expected Results: Session Establishment Rate results obtained with Associated Media with any number of media streams per SIP session are expected to be identical to the Session Establishment Rate results obtained without media in the case where the DUT is running on a platform separate from the Media Relay.

6.4. Session Establishment Rate with Media on DUT

Objective:

To benchmark the Session Establishment Rate of the DUT with zero failures when Associated Media is included in the benchmark test and the media is running through the DUT.

Procedure:

- 1. Configure a DUT according to the test topology shown in Figure 2.
- 2. Set media streams per session to 1.
- Execute benchmarking algorithm as defined in Section 4.10 to get the session establishment rate with media. This rate MUST be recorded using any pertinent parameters as shown in the reporting format of <u>Section 5.1</u>.

Expected Results: Session Establishment Rate results obtained with Associated Media may be lower than those obtained without media in the case where the DUT and the Media Relay are running on the same platform.

6.5. Session Establishment Rate with TLS Encrypted SIP

Objective:

To benchmark the Session Establishment Rate of the DUT with zero failures when using TLS encrypted SIP signaling.

Procedure:

- 1. If the DUT is being benchmarked as a proxy or B2BUA, then configure the DUT in the test topology shown in Figure 1 or Figure 2.
- 2. Configure the tester to enable TLS over the transport being used during benchmarking. Note the ciphersuite being used for TLS and record it in Section 5.1.
- 3. Set media streams per session to 0 (media is not used in this
- 4. Execute benchmarking algorithm as defined in Section 4.10 to get the session establishment rate with TLS encryption.

Expected Results: Session Establishment Rate results obtained with TLS Encrypted SIP may be lower than those obtained with plaintext SIP.

6.6. Session Establishment Rate with IPsec Encrypted SIP

Objective:

To benchmark the Session Establishment Rate of the DUT with zero failures when using IPsec Encrypted SIP signaling.

Procedure:

1. Configure a DUT according to the test topology shown in Figure 1 or Figure 2.

- 2. Set media streams per session to 0 (media is not used in this test).
- 3. Configure tester for IPSec. Note the IPSec profile being used for and record it in Section 5.1.
- 4. Execute benchmarking algorithm as defined in <u>Section 4.10</u> to get the session establishment rate with encryption.

Expected Results: Session Establishment Rate results obtained with IPSec Encrypted SIP may be lower than those obtained with plaintext SIP.

6.7. Registration Rate

Objective:

To benchmark the maximum registration rate the DUT can handle over an extended time period with zero failures.

Procedure:

- 1. Configure a DUT according to the test topology shown in Figure 3.
- Set the registration timeout value to at least 3600 seconds.
- 3. Each register request MUST be made to a distinct address of record (AoR). Execute benchmarking algorithm as defined in Section 4.10 to get the maximum registration rate. This rate MUST be recorded using any pertinent parameters as shown in the reporting format of Section 5.1. For example, the use of TLS or IPSec during registration must be noted in the reporting format. In the same vein, any specific backend processing (use of databases, authentication servers, etc.) SHOULD be recorded as well.

Expected Results: Provides a maximum registration rate.

6.8. Re-Registration Rate

Objective:

To benchmark the re-registration rate of the DUT with zero failures using the same backend processing and parameters used during <u>Section 6.7</u>.

Procedure:

- 1. Configure a DUT according to the test topology shown in Figure 3.
- 2. First, execute test detailed in <u>Section 6.7</u> to register the endpoints with the registrar and obtain the registration rate.
- 3. After at least 5 minutes of Step 2, but no more than 10 minutes after Step 2 has been performed, re-register the same AoRs used in Step 3 of Section 6.7. This will count as a re-

registration because the SIP AoRs have not yet expired.

Expected Results: Note the rate obtained through this test for comparison with the rate obtained in <u>Section 6.7</u>.

7. IANA Considerations

This document does not requires any IANA considerations.

8. Security Considerations

Documents of this type do not directly affect the security of Internet or corporate networks as long as benchmarking is not performed on devices or systems connected to production networks. Security threats and how to counter these in SIP and the media layer is discussed in RFC3550, and RFC3711 and various other drafts. This document attempts to formalize a set of common methodology for benchmarking performance of SIP devices in a lab environment.

9. Acknowledgments

The authors would like to thank Keith Drage and Daryl Malas for their contributions to this document. Dale Worley provided an extensive review that lead to improvements in the documents. We are grateful to Barry Constantine, William Cerveny and Robert Sparks for providing valuable comments during the document's last calls and expert reviews.

W = 0.10
d = max(0.10, w / 2)
DUT_max_sps = 460
                    # Change as needed to set the max sps value
                     # for a DUT
# Returns R, given r (initial session attempt rate).
# E.g., assume that a DUT handles 460 sps in steady state
# and you have saved this code in a file simulate.r. Then,
# start an R session and do the following:
# > source("simulate.r")
\# > find_R(100)
# ... debug output omitted ...
# [1] 458
# Thus, the max sps that the DUT can handle is 458 sps, which is
# close to the absolute maximum of 460 sps the DUT is specified to
# do.
