

The Kerberos Version 5 GSS-API Mechanism

STATUS OF THIS MEMO

This document is an Internet Draft. Internet Drafts are working documents of the Internet Engineering Task Force (IETF), its Areas, and its Working Groups. Note that other groups may also distribute working documents as Internet Drafts.

Internet Drafts are draft documents valid for a maximum of six months. Internet Drafts may be updated, replaced, or obsoleted by other documents at any time. It is not appropriate to use Internet Drafts as reference material or to cite them other than as a "working draft" or "work in progress."

To learn the current status of any Internet-Draft, please check the `lid-abstracts.txt` listing contained in the Internet-Drafts Shadow Directories on `ds.internic.net`, `nic.nordu.net`, `ftp.isi.edu`, or `munari.oz.au`.

Comments on this document should be sent to "`cat-ietf@mit.edu`", the IETF Common Authentication Technology WG discussion list.

ABSTRACT

This specification defines protocols, procedures, and conventions to be employed by peers implementing the Generic Security Service Application Program Interface (as specified in RFCs 1508 and 1509) when using Kerberos Version 5 technology (as specified in [RFC 1510](#)).

ACKNOWLEDGMENTS

Much of the material in this Internet-Draft is based on working documents drafted by John Wray of Digital Equipment Corporation and on discussions, implementation activities, and interoperability testing involving Marc Horowitz of OpenVision Technologies, Ted Ts'o of the Massachusetts Institute of Technology (MIT), and John Wray. Thanks are due to each of these individuals for their contributions towards development and availability of GSS-API support within the Kerberos Version 5 code base.

1. Token Formats

This section discusses protocol-visible characteristics of the GSS-

Internet-Draft

July 1994

API mechanism to be implemented atop Kerberos V5 security technology per [RFC-1508](#) and [RFC-1510](#); it defines elements of protocol for interoperability and is independent of language bindings per [RFC-1509](#).

Tokens transferred between GSS-API peers (for security context management and per-message protection purposes) are defined. The data elements exchanged between a GSS-API endpoint implementation and the Kerberos KDC are not specific to GSS-API usage and are therefore defined within [RFC-1510](#) rather than within this specification.

To support ongoing experimentation, testing, and evolution of the specification, the Kerberos V5 GSS-API mechanism as defined in this and any successor Internet-Drafts will be identified with the following Object Identifier, as defined in [RFC-1510](#), until the specification is advanced to the level of Proposed Standard RFC:

```
{iso(1), org(3), dod(5), internet(1), security(5), kerberosv5(2)}
```

Upon advancement to the level of Proposed Standard RFC, the Kerberos V5 GSS-API mechanism will be identified by an Object Identifier having the value:

```
{iso(1) member-body(2) United States(840) mit(113554) infosys(1)
gssapi(2) krb5(2)}
```

1.1. Context Establishment Tokens

Per [RFC-1508, Appendix B](#), the initial context establishment token will be enclosed within framing as follows:

```
InitialContextToken ::=
[APPLICATION 0] IMPLICIT SEQUENCE {
    thisMech      MechType
        -- MechType is OBJECT IDENTIFIER
        -- representing "Kerberos V5"
    innerContextToken ANY DEFINED BY thisMech
        -- contents mechanism-specific;
        -- ASN.1 usage within innerContextToken
        -- is not required
}
```

The innerContextToken of the initial context token will consist of a

Kerberos V5 KRB_AP_REQ message, preceded by a two-byte token-id (TOK_ID) field, which shall contain the value 01 00.

The above GSS-API framing shall be applied to all tokens emitted by the Kerberos V5 GSS-API mechanism, including KRB_AP_REP, KRB_ERROR,

context-deletion, and per-message tokens, not just to the initial token in a context establishment sequence. While not required by [RFC-1508](#), this enables implementations to perform enhanced error-checking. The innerContextToken field of context establishment tokens for the Kerberos V5 GSS-API mechanism will contain a Kerberos message (KRB_AP_REQ, KRB_AP_REP or KRB_ERROR), preceded by a 2-byte TOK_ID field containing 01 00 for KRB_AP_REQ messages, 02 00 for KRB_AP_REP messages and 03 00 for KRB_ERROR messages.

Relevant KRB_AP_REQ syntax (from [RFC-1510](#)) is as follows:

```
AP-REQ ::= [APPLICATION 14] SEQUENCE {
    pvno [0]          INTEGER,          -- indicates Version 5
    msg-type [1]     INTEGER,          -- indicates KRB_AP_REQ
    ap-options[2]    APOptions,
    ticket[3]        Ticket,
    authenticator[4] EncryptedData
}
```

```
APOptions ::= BIT STRING {
    reserved (0),
    use-session-key (1),
    mutual-required (2)
}
```

```
Ticket ::= [APPLICATION 1] SEQUENCE {
    tkt-vno [0]      INTEGER,          -- indicates Version 5
    realm [1]       Realm,
    sname [2]       PrincipalName,
    enc-part [3]    EncryptedData
}
```

-- Encrypted part of ticket

```
EncTicketPart ::= [APPLICATION 3] SEQUENCE {
    flags[0]        TicketFlags,
    key[1]          EncryptionKey,
```

```

    crealm[2]      Realm,
    cname[3]      PrincipalName,
    transited[4]  TransitedEncoding,
    authtime[5]   KerberosTime,
    starttime[6]  KerberosTime OPTIONAL,
    endtime[7]    KerberosTime,
    renew-till[8] KerberosTime OPTIONAL,
    caddr[9]      HostAddresses OPTIONAL,
    authorization-data[10] AuthorizationData OPTIONAL
}

```

-- Unencrypted authenticator

```

Authenticator ::= [APPLICATION 2] SEQUENCE {
    authenticator-vno[0]  INTEGER,
    crealm[1]            Realm,
    cname[2]             PrincipalName,
    cksum[3]             Checksum OPTIONAL,
    cusec[4]             INTEGER,
    ctime[5]            KerberosTime,
    subkey[6]           EncryptionKey OPTIONAL,
    seq-number[7]       INTEGER OPTIONAL,
    authorization-data[8] AuthorizationData OPTIONAL
}

```

For purposes of this specification, the authenticator shall include the optional sequence number, and the checksum field shall be used to convey the channel bindings. The checksum will have a type of 0x8003 (within the set of negative 16-bit values reserved by Kerberos for application use), and a 24-byte value field, as follows:

Byte	Name	Description
0..3	Lgth	Number of bytes in Bnd field; Currently contains hex 10 00 00 00 (16, represented in little-endian form)
4..19	Bnd	MD5 hash of channel bindings, taken over all non-null components of bindings, in order of declaration. Integer fields within channel bindings are represented in little-endian order for the purposes of the MD5 calculation.
20..23	Flags	Bit vector of context-establishment flags, with values consistent with RFC-1509 , p. 41:

GSS_C_DELEG_FLAG: 1
GSS_C_MUTUAL_FLAG: 2
GSS_C_REPLAY_FLAG: 4
GSS_C_SEQUENCE_FLAG: 8
GSS_C_CONF_FLAG: 16
GSS_C_INTEG_FLAG: 32

The resulting bit vector is encoded into bytes 20..23 in little-endian form.

In computing the contents of the "Bnd" field, the following detailed points apply:

(1) Each integer field shall be formatted into four bytes, using little-endian byte ordering, for purposes of MD5 hash computation.

(2) All input length fields within `gss_buffer_desc` elements of a `gss_channel_bindings_struct`, even those which are zero-valued, shall be included in the hash calculation; the value elements of

`gss_buffer_desc` elements shall be dereferenced, and the resulting data shall be included within the hash computation, only for the case of `gss_buffer_desc` elements having non-zero length specifiers.

(3) If the caller passes the value `GSS_C_NO_BINDINGS` instead of a valid channel bindings structure, the Bnd field shall be set to 16 zero-valued bytes.

It is anticipated that future extensions to this specification may add new features by suffixing additional data following the checksum value field as defined above. In order that such extended implementations may remain interoperable with implementations based on the current specification, implementations of this Internet-Draft shall be capable of accepting checksum value fields with `Lgth` specifiers indicating 24 bytes or greater. Processing procedures for data elements within the checksum value field but after the Flags are not, however, currently defined.

A context establishment sequence based on the Kerberos V5 mechanism will perform one-way authentication (without confirmation or any return token from target to initiator in response to the initiator's

KRB_AP_REQ) if the mutual_req bit is not set in the application's call to gss_init_sec_context(). Applications requiring confirmation that their authentication was successful should request mutual authentication, resulting in a "mutual-required" indication within KRB_AP_REQ AOptions and the setting of the mutual_req bit in the flags field of the authenticator checksum. In response to such a request, the context target will reply to the initiator with a token containing either a KRB_AP_REP or KRB_ERROR, completing the mutual context establishment exchange.

Relevant KRB_AP_REP syntax is as follows:

```
AP-REP ::= [APPLICATION 15] SEQUENCE {
    pvno [0]          INTEGER,          -- represents Kerberos V5
    msg-type [1]     INTEGER,          -- represents KRB_AP_REP
    enc-part [2]     EncryptedData
}
```

```
EncAPRepPart ::= [APPLICATION 27] SEQUENCE {
    ctime [0]        KerberosTime,
    cusec [1]        INTEGER,
    subkey [2]       EncryptionKey OPTIONAL,
    seq-number [3]   INTEGER OPTIONAL
}
```

The optional seq-number element within the AP-REP's EncAPRepPart

shall be included.

The syntax of KRB_ERROR is as follows:

```
KRB-ERROR ::= [APPLICATION 30] SEQUENCE {
    pvno[0]          INTEGER,
    msg-type[1]     INTEGER,
    ctime[2]        KerberosTime OPTIONAL,
    cusec[3]        INTEGER OPTIONAL,
    stime[4]        KerberosTime,
    susec[5]        INTEGER,
    error-code[6]   INTEGER,
    crealm[7]       Realm OPTIONAL,
    cname[8]        PrincipalName OPTIONAL,
    realm[9]        Realm, -- Correct realm
}
```

```

        sname[10]      PrincipalName, -- Correct name
        e-text[11]    GeneralString OPTIONAL,
        e-data[12]    OCTET STRING OPTIONAL
    }

```

Values to be transferred in the error-code field of a KRB-ERROR message are defined in [\[RFC-1510\]](#), not in this specification.

[1.2.](#) Per-Message and Context Deletion Tokens

Three classes of tokens are defined in this section: "Sign" tokens, emitted by calls to `gss_sign()` and consumed by calls to `gss_verify()`, "Seal" tokens, emitted by calls to `gss_seal()` and consumed by calls to `gss_unseal()`, and context deletion tokens, emitted by calls to `gss_delete_sec_context()` and consumed by calls to `gss_process_context_token()`.

Several variants of cryptographic keys are used in generation and processing of per-message tokens:

- (1) context key: uses Kerberos session key (or subkey, if present in authenticator emitted by context initiator) directly
- (2) confidentiality key: forms variant of context key by exclusive-OR with the hexadecimal constant `f0f0f0f0f0f0f0f0`.
- (3) MD2.5 seed key: forms variant of context key by reversing the bytes of the context key (i.e. if the original key is the 8-byte sequence {aa, bb, cc, dd, ee, ff, gg, hh}, the seed key will be {hh, gg, ff, ee, dd, cc, bb, aa}).

[1.2.1.](#) Per-message Tokens - Sign

Use of the `gss_sign()` call yields a token, separate from the user data being protected, which can be used to verify the integrity of that data as received. The token has the following format:

Byte no	Name	Description
0..1	TOK_ID	Identification field. Tokens emitted by <code>gss_sign()</code> contain the hex value 01 01 in this field.

2..3	SGN_ALG	Integrity algorithm indicator. 00 00 - DES MAC MD5 01 00 - MD2.5 02 00 - DES MAC
4..7	Filler	Contains ff ff ff ff
8..15	SND_SEQ	Sequence number field.
16..23	SGN_CKSUM	Checksum of "to-be-signed data", calculated according to algorithm specified in SGN_ALG field.

GSS-API tokens must be encapsulated within the higher-level protocol by the application; no embedded length field is necessary.

1.2.1.1. Checksum

Checksum calculation procedure (common to all algorithms): Checksums are calculated over the data field, logically prepended by the first 8 bytes of the plaintext packet header. The resulting signature binds the data to the packet type and signature algorithm identifier fields.

DES MAC MD5 algorithm: The checksum is formed by computing an MD5 [[RFC-1321](#)] hash over the plaintext data, and then computing a DES-CBC MAC on the 16-byte MD5 result. A standard 64-bit DES-CBC MAC is computed per [[FIPS-PUB-113](#)], employing the context key and a zero IV. The 8-byte result is stored in the SGN_CKSUM field.

MD2.5 algorithm: The checksum is formed by first DES-CBC encrypting a 16-byte zero-block, using a zero IV and a key formed by reversing the bytes of the context key (i.e. if the original key is the 8-byte sequence {aa, bb, cc, dd, ee, ff, gg, hh}, the checksum key will be {hh, gg, ff, ee, dd, cc, bb, aa}). The resulting 16-byte value is logically prepended to the to-be-signed data. A standard MD5 checksum is calculated over the combined data, and the first 8 bytes of the result are stored in the SGN_CKSUM field. (Note: we refer to this algorithm informally as "MD2.5" to connote the fact that it uses half of the 128 bits generated by MD5; use of only a subset of the MD5 bits is intended to protect against the prospect that data could be postfixed to an existing message with corresponding modifications being made to the checksum.)

DES-MAC algorithm: A standard 64-bit DES-CBC MAC is computed on the

plaintext data per [FIPS-PUB-113], employing the context key and a zero IV. Padding procedures to accommodate plaintext data lengths which may not be integral multiples of 8 bytes are defined in [FIPS-PUB-113]. The result is an 8-byte value, which is stored in the SGN_CKSUM field. Support for this algorithm may not be present in all implementations.

1.2.1.2. Sequence Number

Sequence number field: The 8 byte plaintext sequence number field is formed from the sender's four-byte sequence number as follows. If the four bytes of the sender's sequence number are named s0, s1, s2 and s3 (from least to most significant), the plaintext sequence number field is the 8 byte sequence: (s0, s1, s2, s3, di, di, di, di), where 'di' is the direction-indicator (Hex 0 - sender is the context initiator, Hex FF - sender is the context acceptor). The field is then DES-CBC encrypted using the context key and an IV formed from the first 8 bytes of the previously calculated SGN_CKSUM field. After sending a gss_sign() or gss_seal() token, the sender's sequence number is incremented by one.

The receiver of the token will first verify the SGN_CKSUM field. If valid, the sequence number field may be decrypted and compared to the expected sequence number. The repetition of the (effectively 1-bit) direction indicator within the sequence number field provides redundancy so that the receiver may verify that the decryption succeeded.

Since the checksum computation is used as an IV to the sequence number decryption, attempts to splice a checksum and sequence number from different messages will be detected. The direction indicator will detect packets that have been maliciously reflected.

1.2.2. Per-message Tokens - Seal

Use of the gss_seal() call yields a token which encapsulates the input user data (optionally encrypted) along with associated integrity check quantities. The token emitted by gss_seal() consists of an integrity header whose format is identical to that emitted by gss_sign() (except that the TOK_ID field contains the value 02 01), followed by a body portion that contains either the plaintext data (if SEAL_ALG = ff ff) or encrypted data for any other supported value of SEAL_ALG. Currently, only SEAL_ALG = 00 00 is supported, and means that DES-CBC encryption is being used to protect the data.

The gss_seal() token has the following format:

Byte no	Name	Description
0..1	TOK_ID	Identification field. Tokens emitted by <code>gss_seal()</code> contain the hex value 02 01 in this field.
2..3	SGN_ALG	Checksum algorithm indicator. 00 00 - DES MAC MD5 01 00 - MD2.5 02 00 - DES MAC
4..5	SEAL_ALG	ff ff - none 00 00 - DES
6..7	Filler	Contains ff ff
8..15	SND_SEQ	Encrypted sequence number field.
16..23	SGN_CKSUM	Checksum of plaintext padded data, calculated according to algorithm specified in SGN_ALG field.
24..last	Data	encrypted or plaintext padded data

GSS-API tokens must be encapsulated within the higher-level protocol by the application; no embedded length field is necessary.

[1.2.2.1](#). Checksum

Checksum calculation procedure (common to all algorithms): Checksums are calculated over the plaintext padded data field, logically prepended by the first 8 bytes of the plaintext packet header. The resulting signature binds the data to the packet type, protocol version, and signature algorithm identifier fields.

DES MAC MD5 algorithm: The checksum is formed by computing an MD5 hash over the plaintext padded data, and then computing a DES-CBC MAC on the 16-byte MD5 result. A standard 64-bit DES-CBC MAC is computed per [FIPS-PUB-113], employing the context key and a zero IV. The 8-byte result is stored in the SGN_CKSUM field.

MD2.5 algorithm: The checksum is formed by first DES-CBC encrypting a 16-byte zero-block, using a zero IV and a key formed by reversing the bytes of the context key (i.e., if the original key is the 8-byte sequence {aa, bb, cc, dd, ee, ff, gg, hh}, the checksum key will be {hh, gg, ff, ee, dd, cc, bb, aa}). The resulting 16-byte value is logically pre-pended to the "to-be-signed data". A standard MD5 checksum is calculated over the combined data, and the first 8 bytes of the result are stored in the SGN_CKSUM field.

DES-MAC algorithm: A standard 64-bit DES-CBC MAC is computed on the plaintext padded data per [FIPS-PUB-113], employing the context key and a zero IV. The plaintext padded data is already assured to be an

integral multiple of 8 bytes; no additional padding is required or applied in order to accomplish MAC calculation. The result is an 8-

Internet-Draft

July 1994

byte value, which is stored in the SGN_CKSUM field. Support for this algorithm may not be present in all implementations.

1.2.2. Sequence Number

Sequence number field: The 8 byte plaintext sequence number field is formed from the sender's four-byte sequence number as follows. If the four bytes of the sender's sequence number are named s0, s1, s2 and s3 (from least to most significant), the plaintext sequence number field is the 8 byte sequence: (s0, s1, s2, s3, di, di, di, di), where 'di' is the direction-indicator (Hex 0 - sender is the context initiator, Hex FF - sender is the context acceptor).

The field is then DES-CBC encrypted using the context key and an IV formed from the first 8 bytes of the SEAL_CKSUM field.

After sending a gss_sign() or gss_seal() token, the sender's sequence numbers are incremented by one.

1.2.2.3: Padding

Data padding: Before encryption and/or signature calculation, plaintext data is padded to the next highest multiple of 8 bytes, by appending between 1 and 8 bytes, the value of each such byte being the total number of padbytes. For example, given data of length 20 bytes, four pad bytes will be appended, and each byte will contain the hex value 04. An 8-byte random confounder is prepended to the data, and signatures are calculated over the resulting padded plaintext.

After padding, the data is encrypted according to the algorithm specified in the SEAL_ALG field. For SEAL_ALG=DES (the only non-null algorithm currently supported), the data is encrypted using DES-CBC, with an IV of zero. The key used is derived from the established context key by XOR-ing the context key with the hexadecimal constant f0f0f0f0f0f0f0.

1.2.3. Context deletion token

The token emitted by `gss_delete_sec_context()` is based on the packet format for tokens emitted by `gss_sign()`. The context-deletion token has the following format:

Byte no	Name	Description
0..1	TOK_ID	Identification field. Tokens emitted by <code>gss_delete_sec_context()</code> contain the hex value 01 02 in this field.

2..3	SGN_ALG	Integrity algorithm indicator. 00 00 - DES MAC MD5 01 00 - MD2.5 02 00 - DES MAC
4..7	Filler	Contains ff ff ff ff
8..15	SND_SEQ	Sequence number field.
16..23	SGN_CKSUM	Checksum of "to-be-signed data", calculated according to algorithm specified in SGN_ALG field.

SGN_ALG and SND_SEQ will be calculated as for tokens emitted by `gss_sign()`. The SGN_CKSUM will be calculated as for tokens emitted by `gss_sign()`, except that the user-data component of the "to-be-signed" data will be a zero-length string.

2. Name Types and Object Identifiers

This section discusses the name types which may be passed as input to the Kerberos V5 GSS-API mechanism's `gss_import_name()` call, and their associated identifier values. It defines interface elements in support of portability, and assumes use of C language bindings per [RFC-1509](#). In addition to specifying OID values for name type identifiers, symbolic names are included and recommended to GSS-API implementors in the interests of convenience to callers. It is understood that not all implementations of the Kerberos V5 GSS-API mechanism need support all name types in this list, and that additional name forms will likely be added to this list over time. Further, the definitions of some or all name types may later migrate to other, mechanism-independent, specifications. The occurrence of a name type in this specification is specifically not intended to suggest that the type may be supported only by an implementation of the Kerberos V5 mechanism. In particular, the occurrence of the

string "_KRB5_" in the symbolic name strings constitutes a means to unambiguously register the name strings, avoiding collision with other documents; it is not meant to limit the name types' usage or applicability.

For purposes of clarification to GSS-API implementors, this section's discussion of some name forms describes means through which those forms can be supported with existing Kerberos technology. These discussions are not intended to preclude alternative implementation strategies for support of the name forms within Kerberos mechanisms or mechanisms based on other technologies. To enhance application portability, implementors of mechanisms are encouraged to support name forms as defined in this section, even if their mechanisms are independent of Kerberos V5.

[2.1](#). Mandatory Name Forms

Linn

Document Expiration: 31 January 1995

[Page 11]

Internet-Draft

July 1994

This section discusses name forms which are to be supported by all conformant implementations of the Kerberos V5 GSS-API mechanism.

[2.1.1](#) Kerberos Principal Name Form

This name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) krb5(2) krb5_name(1)}. The recommended symbolic name for this type is "GSS_KRB5_NT_PRINCIPAL_NAME".

This name type represents any valid Kerberos name parseable by the Kerberos V5 routine krb5_parse_name; such names have characteristics as follows: Components of a name are separated by `/`. The separator `@` may be used instead of `/`, signifying that the remainder of the string following the `@` is to be interpreted as a realm identifier; if no `@` is encountered, the name is interpreted in the context of the local realm. Once a `@` is encountered, a non-null realm name, with no embedded `/` separators, must follow. The `\" character is used to quote the immediately-following character.

[2.1.2](#). Host-Based Service Name Form

This name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) generic(1) service_name(4)}. The recommended symbolic name for this

type is "GSS_KRB5_NT_HOSTBASED_SERVICE_NAME".

This name type is used to represent services associated with host computers. The two parts of this name form, which is constructed as:

service@hostname

can be supported with Kerberos V5 technology by passing those name parts as the first two arguments to the Kerberos V5 library function `krb5_sname_to_principal`, with the type argument set to `KRB5_NT_SRV_HST`. This processing canonicalizes the hostname (by attempting a DNS lookup and using the fully-qualified domain name returned, or using the name as input should the DNS lookup fail), and ensures that its characters are lower case. No facility is currently provided for explicit specification of a Kerberos realm.

[2.2. Optional Name Forms](#)

This section discusses additional name forms which may optionally be supported by implementations of the Kerberos V5 GSS-API mechanism. It is recognized that the set of name forms cited here are derived from UNIX(tm) operating system platforms; some listed forms may be irrelevant to non-UNIX platforms, and definition of additional forms

corresponding to such platforms may also be appropriate. It is also recognized that OS-specific functions outside GSS-API are likely to exist in order to perform translations among these forms, and that GSS-API implementations supporting these forms may themselves be layered atop such OS-specific functions. Inclusion of this support within GSS-API implementations is intended as a convenience to applications.

[2.2.1. User Name Form](#)

This name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) generic(1) user_name(1)}. The recommended symbolic name for this type is "GSS_KRB5_NT_USER_NAME".

This name type is used to indicate a named user on a local system. Its interpretation is OS-specific. This name form is constructed as:

username

Assuming that users' principal names are the same as their local operating system names, an implementation of `gss_import_name()` based on Kerberos V5 technology can process names of this form by postfixing an "@" sign and the name of the local realm.

2.2.2. Machine UID Form

This name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) generic(1) machine_uid_name(2)}. The recommended symbolic name for this type is "GSS_KRB5_NT_MACHINE_UID_NAME".

This name type is used to indicate a numeric user identifier corresponding to a user on a local system. Its interpretation is OS-specific. The `gss_buffer_desc` representing a name of this type should contain a locally-significant `uid_t`, represented in host byte order. The `gss_import_name()` operation resolves this `uid` into a username, which is then treated as the User Name Form.

2.2.3. String UID Form

This name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) generic(1) string_uid_name(3)}. The recommended symbolic name for this type is "GSS_KRB5_NT_STRING_UID_NAME".

This name type is used to indicate a string of digits representing the numeric user identifier of a user on a local system. Its

interpretation is OS-specific. This name type is similar to the Machine UID Form, except that the buffer contains a string representing the `uid_t`.

2.3. Internal Name Object Support

This section defines optional routines for use by implementations of the Kerberos V5 mechanism which enable support for input and output of Kerberos principal objects as naming structures, and defines an identifier for this name form. Implementors should note that use of these routines, and associated mechanism-specific name objects, by an

application is a construct unlikely to be portable to other mechanisms.

[2.3.1.](#) GSS_Import_internal_name routine

```
OM_uint32      gss_import_internal_name(
                OM_uint32 minor_status,
                void * input_name,
                gss_oid_t name_type,
                gss_name_t * output_name);
```

Converts an implementation-specific name <input_name> into a gss_name_t. The name_type argument specifies the format of input_name.

[2.3.2.](#) GSS_Export_internal_name routine

```
OM_uint32      gss_export_internal_name(
                OM_uint32 minor_status,
                gss_name_t input_name,
                gss_oid_t desired_name_type,
                void ** output_name);
```

Converts a gss_name_t name into an implementation-specific representation. The desired representation is specified by the <desired_name_type> argument. Note that it may not be possible to convert some gss_name_t values into some supported internal name types.

[2.3.3.](#) krb5_principal Form

This mechanism-internal name form shall be represented by the Object Identifier {iso(1) member-body(2) United States(840) mit(113554) infosys(1) gssapi(2) krb5(2) krb5_principal(2)}. The recommended symbolic name for this type is "GSS_KRB5_NT_PRINCIPAL". A name of this type shall be referenced via a krb5_principal object (which is defined within the MIT Kerberos V5 implementation as a pointer to a

krb5_principal_data object), with the krb5_principal's data type cast to (void *).

[3.](#) Parameter Definitions

This section defines parameter values used by the Kerberos V5 GSS-API mechanism. It defines interface elements in support of portability, and assumes use of C language bindings per [RFC-1509](#).

[3.1.](#) Minor Status Codes

This section recommends common symbolic names for `minor_status` values to be returned by the Kerberos V5 GSS-API mechanism. Use of these definitions will enable independent implementors to enhance application portability across different implementations of the mechanism defined in this specification. (In all cases, implementations of `gss_display_status()` will enable callers to convert `minor_status` indicators to text representations.) Each implementation should make available, through include files or other means, a facility to translate these symbolic names into the concrete values which a particular GSS-API implementation uses to represent the `minor_status` values specified in this section. It is recognized that this list may grow over time, and that the need for additional `minor_status` codes specific to particular implementations may arise.

[3.1.1.](#) Non-Kerberos-specific codes

```
GSS_KRB5_S_G_BAD_SERVICE_NAME
    /* "No @ in SERVICE-NAME name string" */
GSS_KRB5_S_G_BAD_STRING_UID
    /* "STRING-UID-NAME contains nondigits" */
GSS_KRB5_S_G_NOUSER
    /* "UID does not resolve to username" */
GSS_KRB5_S_G_VALIDATE_FAILED
    /* "Validation error" */
GSS_KRB5_S_G_BUFFER_ALLOC
    /* "Couldn't allocate gss_buffer_t data" */
GSS_KRB5_S_G_BAD_MSG_CTX
    /* "Message context invalid" */
GSS_KRB5_S_G_WRONG_SIZE
    /* "Buffer is the wrong size" */
GSS_KRB5_S_G_BAD_USAGE
    /* "Credential usage type is unknown" */
GSS_KRB5_S_G_UNKNOWN_QOP
    /* "Unknown quality of protection specified" */
```

[3.1.2.](#) Kerberos-specific-codes

```
GSS_KRB5_S_KG_CCACHE_NOMATCH
    /* "Principal in credential cache does not match desired name" */
GSS_KRB5_S_KG_KEYTAB_NOMATCH
    /* "No principal in keytab matches desired name" */
GSS_KRB5_S_KG_TGT_MISSING
    /* "Credential cache has no TGT" */
GSS_KRB5_S_KG_NO_SUBKEY
    /* "Authenticator has no subkey" */
GSS_KRB5_S_KG_CONTEXT_ESTABLISHED
    /* "Context is already fully established" */
GSS_KRB5_S_KG_BAD_SIGN_TYPE
    /* "Unknown signature type in token" */
GSS_KRB5_S_KG_BAD_LENGTH
    /* "Invalid field length in token" */
GSS_KRB5_S_KG_CTX_INCOMPLETE
    /* "Attempt to use incomplete security context" */
```

3.2. Quality of Protection Values

The following Quality of Protection (QOP) values are currently defined for the Kerberos V5 GSS-API mechanism, and are used as input to `gss_sign()` and `gss_seal()` to select among alternate integrity checking algorithms. Additional QOP values corresponding to additional integrity and/or confidentiality algorithms may be added in future versions of this specification.

```
GSS_KRB5_INTEG_C_QOP_MD5
    /* Integrity using partial MD5 ("MD2.5") of plaintext */
GSS_KRB5_INTEG_C_QOP_DES_MD5
    /* Integrity using DES MAC of MD5 of plaintext */
GSS_KRB5_INTEG_C_QOP_DES_MAC
    /* Integrity using DES MAC of plaintext */
```

3.3. Buffer Sizes

All implementations of this specification shall be capable of accepting buffers of at least 2 Kbytes as input to `GSS_Sign()`, `GSS_Verify()`, and `GSS_Seal()`, and shall be capable of accepting the `output_token` generated by `GSS_Seal()` for a 2 Kbyte input buffer as input to `GSS_Unseal()`. Support for larger buffer sizes is optional but recommended.

4. Security Considerations

Security issues are discussed throughout this memo.
