   Interworking Requirements to Support operation of MPLS-TE over GMPLS
                                Networks

               draft-ietf-ccamp-mpls-gmpls-interwork-reqts-04.txt

Status of this Memo

   By submitting this Internet-Draft, each author represents that any
   applicable patent or other IPR claims of which he or she is aware
   have been or will be disclosed, and any of which he or she becomes
   aware will be disclosed, in accordance with Section 6 of BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF), its areas, and its working groups. Note that
   other groups may also distribute working documents as
   Internet-Drafts.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

Abstract

   Operation of a Multiprotocol Label Switching (MPLS) traffic
   engineering (TE) network as a client network to a Generalized MPLS
   (GMPLS) network has enhanced operational capabilities compared to
   those provided by a co-existent protocol model (i.e., operation of
   MPLS-TE over an independently managed transport layer).

   The GMPLS network may be a packet or a non-packet network, and may
   itself be a multi-layer network supporting both packet and non-packet
   technologies. A MPLS-TE Label Switched Path (LSP) originates and
   terminates on an MPLS Label Switching Router (LSR). The GMPLS network
   provides transparent transport for the end-to-end MPLS-TE LSP.

   This document describes a framework and Service Provider requirements
   for operating MPLS-TE networks over GMPLS networks.

Table of Contents

[1](#). Introduction

Multiprotocol Label Switching traffic engineering (MPLS-TE) networks
are often deployed over transport networks such that the transport
networks provide connectivity between the Label Switching Routers
(LSRs) in the MPLS-TE network. Increasingly, these transport networks
are operated using a Generalized Multiprotocol Label Switching
(GMPLS) control plane, and label Switched Paths (LSPs) in the GMPLS
network provide connectivity as virtual data links advertised as TE
links in the MPLS-TE network.

GMPLS protocols were developed as extensions to MPLS-TE protocols.
MPLS-TE is limited to the control of packet switching networks, but

GMPLS can also control technologies at layers one and two.

The GMPLS network may be managed by an operator as a separate network
(as it may have been when it was under management plane control
before the use of GMPLS as a control plane), but optimizations of
management and operation may be achieved by coordinating the use of
the MPLS-TE and GMPLS networks and operating the two networks with a
close client/server relationship.

GMPLS LSP setup may triggered by the signaling of MPLS-TE LSPs in the
MPLS-TE network so that the GMPLS network is reactive to the needs of
the MPLS-TE network. The triggering process can be under the control
of operator policies without needing direct intervention by an
operator.

The client/server configuration just described can also apply in
migration scenarios for MPLS-TE packet switching networks that are
being migrated to be under GMPLS control. [MIGRATE] describes a
migration scenario called the Island Model. In this scenario, groups
of nodes (islands) are migrated from the MPLS-TE protocols to the
GMPLS protocols and operate entirely surrounded by MPLS-TE nodes (the
sea). This scenario can be effectively managed as a client/server
network relationship using the framework described in this document.

In order to correctly manage the dynamic interaction between the MPLS
and GMPLS networks, it is necessary to understand the operational
requirements and the control that the operator can impose. Although
this problem is very similar to the multi-layer networks described in
[MLN], it must be noted that those networks operate GMPLS protocols
in both the client and server networks which facilitates smoother
interworking. Where the client network uses MPLS-TE protocols over
the GMPLS server network there is a need to study the interworking of
the two protocol sets.

This document examines the protocol requirements for protocol
interworking to operate an MPLS-TE network as a client network over a
GMPLS server network, and provides a framework for such operations.

1.1 Terminology

Although this Informational document is not a protocol specification,
The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in [RFC2119] for clarity
of exposure of the requirements.

2. Reference Model

The reference model used in this document is shown in Figure 1. It can easily be seen that the interworking between MPLS-TE and GMPLS protocols must occur on a node and not on a link. Nodes on the interface between the MPLS-TE and GMPLS networks must be responsible for handling both protocol sets and for providing any protocol interworking that is required. We call these nodes Border Routers.

```

          |                                                |
          |<---------------------------------------------->|
                      End-to-End MPLS-TE LSP
```
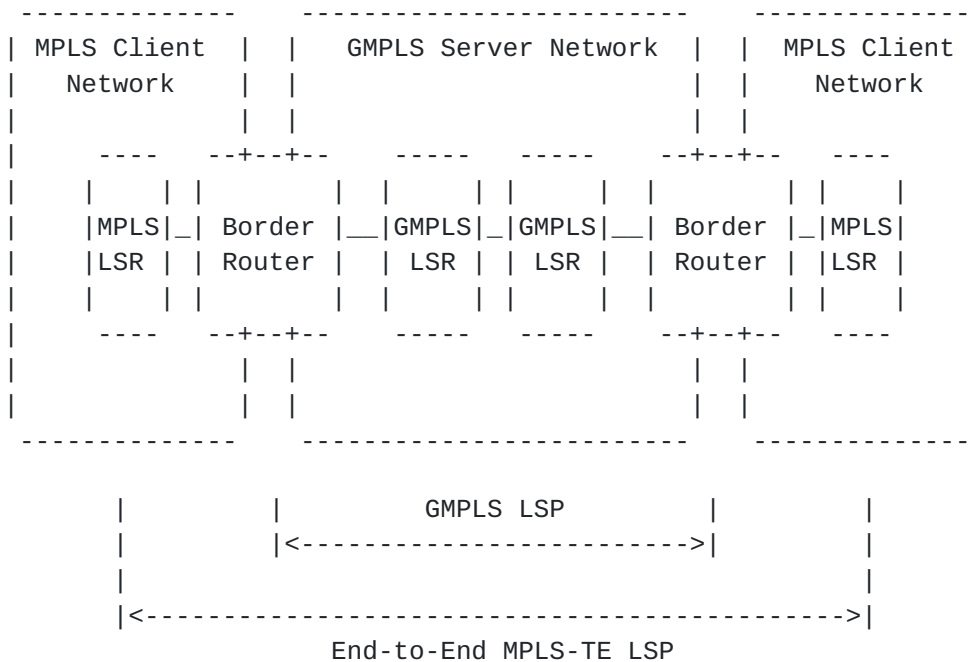

Figure 1. Reference model of MPLS-TE/GMPLS interworking

MPLS-TE network connectivity is provided through a GMPLS LSP which is created between Border Routers. End-to-end connectivity between MPLS LSRs in the client MPLS-TE networks is provided by an MPLS-TE LSP that is carried across the MPLS-TE network by the GMPLS LSP using hierarchical LSP techniques [RFC4206], LSP stitching segments [STITCH], or a contiguous LSP. LSP stitching segments and contiguous LSPs are only available where the GMPLS network is a packet switching network.

3. Detailed Requirements

   This section describes detailed requirements for MPLS-TE/GMPLS
   interworking in support of the reference model shown in Figure 1.

   The functional requirements for GMPLS-MPLS interworking described in
   this section must be met by any device participating in the
   interworking. This may include routers, servers, network management
   devices, path computation elements, etc.

3.1 End-to-End Signaling

   The solution MUST be able to preserve MPLS signaling information
   signaled within the MPLS-TE client network at the start of the MPLS-
   TE LSP, and deliver it on the other side of the GMPLS server network
   for use within the MPLS-TE client network at the end of the MPLS-TE
   LSP. This may require protocol mapping (and re-mapping), protocol
   tunneling, or the use of remote protocol adjacencies.

3.2 Triggered Establishment of GMPLS LSPs

   The solution MUST provide the ability to establish end-to-end MPLS-
   TE LSPs over a GMPLS server network. It SHOULD be possible for GMPLS
   LSPs across the core network to be set up between Border Routers
   triggered by the signaling of MPLS-TE LSPs in the client network, and
   in this case, policy controls MUST be made available at the border
   routers so that the operator of the GMPLS network can manage how core
   network resources are utilized. GMPLS LSPs MAY also be pre-
   established as the result of management plane control.

   Note that multiple GMPLS LSPs may be set up between a given pair of
   Border Routers in support of connectivity in the MPLS client network.
   If these LSPs are advertised as TE links in the client network, the
   use of link bundling [RFC4201] can reduce any scaling concerns
   associated with the advertisements.

   The application of the Path Computation Element (PCE) [RFC4655] in
   the context of an inter-layer network [PCE-INTER-LAYER] may be
   considered to determine an end-to-end LSP with triggered GMPLS
   segment or tunnel.

3.3 Diverse Paths for End-to-End MPLS-TE LSPs

   The solution SHOULD provide the ability to establish end-to-end MPLS-
   TE LSPs having diverse paths for protection of the LSP traffic. This
   means that MPLS-TE LSPs SHOULD be kept diverse both within the client
   MPLS-TE network and as they cross the server GMPLS network. This
   means that there SHOULD be a mechanism to request the provision of
   diverse GMPLS LSPs between a pair of Border Routers to provide

protection of the GMPLS span, but also that there SHOULD be a way to
keep GMPLS LSPs between different Border Routers disjoint.

3.4 Advertisement of MPLS-TE Information via the GMPLS Network

The solution SHOULD provide the ability to exchange advertisements of
TE information between MPLS-TE client networks across the GMPLS
server network.

The advertisement of TE information from within an MPLS-TE client
network to all LSRs in the client network enables a head end LSR to
compute an optimal path for an LSP to a tail end LSR that is reached
over the GMPLS server network.

Where there is more than one client MPLS-TE network, the TE
information from separate MPLS-TE networks MUST be kept private,
confidential and secure.

3.5 Selective Advertisement of MPLS-TE Information via a Border Node

The solution SHOULD provide the ability to distribute TE reachability
information from the GMPLS server network to MPLS-TE networks
selectively. This information is useful for the LSRs in the MPLS-TE
networks to compute paths that cross the GMPLS server network and to
select the correct Border Routers to provide connectivity.

The solution MUST NOT distribute TE information from within a non-PSC
(Packet Switch Capable) GMPLS server network to any client MPLS-TE
network as that information may cause confusion and selection of
inappropriate paths.

The use of PCE [RFC4655] may provide a solution for non-PSC GMPLS
networks supporting PSC MPLS networks.

3.6 Interworking of MPLS-TE and GMPLS Protection

If an MPLS-TE LSP is protected using MPLS Fast Reroute (FRR)
[RFC4090], then similar protection MUST be provided over the GMPLS
island. Operator and policy controls SHOULD be made available at the
Border Router to determine how suitable protection is provided in the
GMPLS island.

3.7 Independent Failure Recovery and Reoptimization

The solution SHOULD provide failure recovery and reoptimization in
the GMPLS server network without impacting the MPLS-TE client network
and vice versa. That is, it SHOULD be possible to recover from a
fault within the GMPLS island or to reoptimize the path across the
GMPLS island without requiring signaling activity within the MPLS-TE
client network. Similarly, it SHOULD be possible to perform recovery

or reoptimization within the MPLS-TE client network without requiring
signaling activity within the GMPLS server networks.

If a failure in the GMPLS server network can not be repaired
transparently, some kind of notification of the failure SHOULD be
transmitted to MPLS-TE network.

3.8 Complexity and Risks

The solution SHOULD NOT introduce unnecessary complexity to the
current operating network to such a degree that it would affect the
stability and diminish the benefits of deploying such a solution in
service provider networks.

3.9 Scalability Considerations

The solution MUST scale well with consideration to at least the
following metrics.

- The number of GMPLS-capable nodes (i.e., the size of the GMPLS
  server network).
- The number of MPLS-TE-capable nodes (i.e., the size of the MPLS-TE
  client network).
- The number of MPLS-TE client networks.
- The number of GMPLS LSPs.
- The number of MPLS-TE LSPs.

3.10 Performance Considerations

The solution SHOULD be evaluated with regard to the following
criteria.

- Failure and restoration time.
- Impact and scalability of the control plane due to added
  overheads.
- Impact and scalability of the data/forwarding plane due to added
  overheads.

3.11 Management Considerations

Manageability of the deployment of an MPLS-TE client network over
GMPLS server network MUST addresses the following considerations.

- Need for coordination of MIB modules used for control plane
  management and monitoring in the client and server networks.
- Need for diagnostic tools that can discover and isolate faults
  across the border between the MPLS-TE client and GMPLS server
  networks.

4. Security Considerations

Border routers in the model described in this document are present on
administrative domain boundaries. That is, the administrative
boundary does not lie on a link as it might in the inter-Autonomous
System case seen in IP networks. Thus, many security concerns for the
inter-domain exchange of control plane messages do not arise in this
model - the border router participates fully in both the MPLS and the
GMPLS network and must participate in the security procedures of both
networks. Security considerations for MPLS-TE and GMPLS protocols are
discussed in [SECURITY].

However, policy considerations at the border routers are very
important and may be considered to form part of the security of the
networks. In particular, the server network (the GMPLS network) may
wish to protect itself from behavior in the client network (such as
frequent demands to set up and tear down server LSPs) by appropriate
policies implemented at the border routers. It should be observed
that, because the border routers form part of both networks, they are
trusted in both networks, and policies configured (whether locally or
centrally) for use by a border router are expected to be observed.

Nevertheless, authentication and access controls for operators will
be particularly important at border routers. Operators of the client
MPLS-TE network MUST NOT be allowed to configure the server GMPLS
network (including setting server network policies), and operators of
the server GMPLS network MUST NOT be able configure the client MPLS-
TE network. Obviously, it SHOULD be possible to grant an operator
privileges in both networks. It may also be desirable to give
operators of one network access to (for example) status information
about the other network.

Mechanisms for authenticating operators and providing access controls
do not form part of the responsibilities of the GMPLS protocol set,
and will depend on the management plane protocols and techniques
implemented.

5. Recommended Solution Architecture

The recommended solution architecture to meet the requirements set
out in Section 3 is known as the Border Peer Model. This architecture
is a variant of the Augmented Model described in [RFC3945]. The
remainder of this document presents an overview of this architecture.

In the Augmented Model, routing information from the lower layer
(server) network is filtered at the interface to the higher layer
(client) network and a subset of the information is distributed
within the higher layer network.

In the Border Peer Model, the interface between the client and server networks is the Border Router. This router has visibility of the routing information in the server network yet also participates as a peer in the client network. Thus the Border Router has full visibility into both networks. However, the Border Router does not distribute server routing information into the client network, nor does it distribute client routing information into the server network.

The Border Peer Model may also be contrasted with the Overlay Model [RFC3945]. In this model there is a protocol request/response interface (the user network interface - UNI) between the client and server networks. [RFC4208] shows how this interface may be supported by GMPLS protocols operated between client edge and server edge routers while retaining the routing information within the server network. That is, in the Overlay Model there is no exchange of routing or reachability information between client and server networks, and no network element has visibility into both client and server networks. The Border Peer Model can be viewed as placing the UNI within the Border Router thus giving the Border Router peer capabilities in both the client and server network.

5.1 Use of Contiguous, Hierarchical, and Stitched LSPs

All three LSP types MAY be supported in the Border Peer Model, but contiguous LSPs are the hardest to support because they require protocol mapping between the MPLS-TE client network and the GMPLS server network. Such protocol mapping can be achieved currently since MPLS-TE signaling protocols are a subset of GMPLS, but this mechanism is not future-proofed.

Contiguous and stitched LSPs can only be supported where the GMPLS server network has the same switching type (that is, packet switching) as the MPLS-TE network. Requirements for independent failure recovery within the GMPLS island require the use of loose path reoptimization techniques [RFC4736] and end-to-end make-before-break [RFC3209] which will not provide rapid recovery.

For these reasons, the use of hierarchical LSPs across the server network is RECOMMENDED for the Border Peer Model, but see the discussion of Fast Reroute protection in Section 5.3.

5.2 MPLS-TE Control Plane Connectivity

Control plane connectivity between MPLS-TE LSRs connected by a GMPLS island in the Border Peer Model MAY be provided by the control channels of the GMPLS network. If this is done, a tunneling mechanism (such as GRE [RFC2784]) SHOULD be used to ensure that MPLS-TE information is not consumed by the GMPLS LSRs. But care is required

to avoid swamping the control plane of the GMPLS network with MPLS-TE

control plane (particularly routing) messages.

In order to ensure scalability, control plane messages for the MPLS-TE client network MAY be carried between Border Routers in a single hop MPLS-TE LSP routed through the data plane of the GMPLS server network.

5.3 Fast Reroute Protection

If the GMPLS network is packet switching, Fast Reroute protection can be offered on all hops of a contiguous LSP. If the GMPLS network is packet switching then all hops of a hierarchical GMPLS LSP or GMPLS stitching segment can be protected using Fast Reroute. If the end-to-end MPLS-TE LSP requests Fast Reroute protection, the GMPLS packet switching network SHOULD provide such protection.

However, note that it is not possible to provide FRR node protection of the upstream Border Router without careful consideration of available paths, and protection of the downstream Border Router is not possible where hierarchical LSPs or stitching segments are used.

Note further that Fast Reroute is not available in non-packet technologies. However, other protection techniques are supported by GMPLS for non-packet networks and are likely to provide similar levels of protection.

The limitations of FRR need careful consideration by the operator and may lead to the decision to provide end-to-end protection for the MPLS-TE LSP.

5.4 GMPLS LSP Advertisement

In the Border Peer Model, the LSPs established by the Border Routers in the GMPLS server network SHOULD be advertised in the MPLS-TE client network as real or virtual links. In case real links are advertised into the MPLS-TE client network, the Border Routers in the MPLS-TE client network MAY establish IGP neighbors. The Border Routers MAY automatically advertise the GMPLS LSPs when establishing them.

5.5 GMPLS Deployment Considerations

The Border Peer Model does not require the existing MPLS-TE client network to be GMPLS aware and does not affect on the operation and management of the existing MPLS-TE client network. Only border routers need to be upgraded with the GMPLS functionality. In this fashion, the Border Peer Model renders itself for incremental deployment of the GMPLS server network, without requiring reconfiguration of existing areas/ASes, changing operation of IGP and BGP or software upgrade of the existing MPLS-TE client network.

6. IANA Considerations

This requirements document makes no requests for IANA action.

7. Acknowledgments

The author would like to express thanks to Raymond Zhang, Adrian
Farrel, and Deborah Brungard for their helpful and useful comments
and feedback.
