# DECoupled Application Data Enroute (DECADE) Problem Statement draft-ietf-decade-problem-statement-04

#### Abstract

Peer-to-peer (P2P) applications have become widely used on the Internet today and make up a large portion of the traffic in many networks. In P2P applications, one technique for reducing the transit and uplink P2P traffic is to introduce storage capabilities within the network (the download traffic may increase because the innetwork storage is likely much better connected). Traditional caches (e.g., P2P and Web caches) provide such storage, but they are complex (due to explicitly supporting individual P2P application protocols and cache refreshing mechanisms) and they do not have the feature to allow users to manage access to content in the cache. For example, Content Providers cannot easily control cache access and resource usage policies to satisfy their own requirements. In this document, a content provider is also the user of in-network storage. This document discusses the introduction of in-network storage for P2P applications, and shows the need for a standard protocol for accessing this storage. It can also be used by other applications with similar requirements.

## Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of  $\underline{\mathsf{BCP}}$  78 and  $\underline{\mathsf{BCP}}$  79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <a href="http://datatracker.ietf.org/drafts/current/">http://datatracker.ietf.org/drafts/current/</a>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 14, 2012.

#### 1. Introduction

P2P applications, including both P2P streaming and P2P filesharing applications, make up a large fraction of the traffic in many ISP networks today. One way to reduce bandwidth usage by P2P applications is to introduce storage capabilities in the networks. Allowing P2P applications to store and retrieve data from inside networks can reduce traffic on the last-mile uplink, as well as backbone and transit links.

P2P caches provide in-network storage and have been deployed in some networks. But the current P2P caching architecture poses challenges to both P2P cache vendors and P2P application developers. For P2P cache vendors, it is challenging to support a number of continuously evolving P2P application protocols, due to lack of documentation, ongoing protocol changes, and rapid introduction of new features by P2P applications. For P2P applications, closed P2P caching systems limit P2P applications from effectively utilizing in-network storage. In particular, P2P caches typically do not allow users to explicitly store content into in-network storage. They do not allow users to implement control over the content that has been placed into the in-network storage either.

Both of these challenges can be effectively addressed by using an open, standard protocol to access in-network storage. P2P applications can store and retrieve content in the in-network storage, as well as control resources (e.g., bandwidth, connections) consumed by peers in a P2P application. As a simple example, a peer of a P2P application may upload to other peers through its in-network storage, saving its usage of last-mile uplink bandwidth.

In this document, we distinguish between two functional components of the native P2P application protocol: signaling and data access. Signaling includes operations such as handshaking and discovering peer and content availability. The data access component transfers content from one peer to another.

This document introduces DECADE, a standard interface for various P2P applications to access storage and data transport services in the network to improve their efficiency and reduce load on the network infrastructure.

With DECADE, P2P applications can still use their native protocols for signaling and data transport. However, they may use a standard protocol for data access incorporating in-network storage, and fall back to their native data transport protocols if in-network storage is not available or not used.

In essence, an open, standard protocol to access in-network storage provides an alternative mechanism for P2P application data access that is decoupled from P2P application control and signaling. This decoupling leads to many advantages, which is explained further in Section 4.

And further, either the existing P2P cache or any new type of innetwork storage should be deployed near the edge of the ISP's network so as to gain better performance.

## 2. Terminology and Concepts

The following terms have special meaning in the definition of the innetwork storage system.

In-network Storage: A service inside a network that provides storage and bandwidth to network applications. In-network storage may reduce upload/transit/backbone traffic and improve network application performance.

P2P Cache (Peer to Peer Cache): a kind of in-network storage that understands the signaling and transport of specific P2P application protocols, it caches the content for those specific P2P applications in order to serve peers and reduce traffic on certain links.

Content Publisher: An entity that originates content.

## 3. The Problems

The emergence of peer-to-peer (P2P) as a major network application (esp. P2P file sharing and streaming apps) has led to substantial opportunities. The P2P paradigm can be utilized in designing highly scalable and robust applications at low cost, compared with traditional client-server paradigms. For example, CNN reported that P2P streaming by Octoshape played a major role in its distribution of the historic inauguration address of President Obama[Octoshape]. PPLive, one of the largest P2P streaming vendors, is able to distribute large-scale, live streaming programs to more than 2 million users with only a handful of servers[PPLive].

However, P2P applications also face substantial design challenges. A particular problem facing P2P applications is the substantial stress that they place on the network infrastructure. Also, lack of infrastructure support can lead to unstable P2P application performance during peer churns and flash crowd. Here flash crowds

means a large group of application users begin to access the same service during a very short period of time, which is a challenge to the system. Below we elaborate on the problems in more detail.

# 3.1. P2P infrastructural stress and inefficiency

A particular problem of the P2P paradigm is the stress that P2P application traffic places on the infrastructure of Internet service providers (ISPs). Multiple measurements (e.g., [ipoque]) have shown that P2P traffic has become a major type of traffic on some networks. Furthermore, network-agnostic peering (P2P transmission level) leads to unnecessary traversal across network domains or spanning the backbone of a network, leading to network inefficiency [RFC5693].

An ALTO (Application Layer Traffic Optimization) server provides P2P applications with network information so that they can perform better-than-random initial peer selection [RFC5693]. However, there are limitations on what ALTO can achieve alone. For example, network information alone cannot reduce P2P traffic in access networks, as the total access upload traffic is equal to the total access download traffic in a pure P2P system. On the other hand, it is reported that P2P traffic is becoming the dominant traffic on the access networks of some networks, reaching as high as 50-60% at the down-links and 60-90% at the uplinks ([DCIA], [ICNP], [ipoque.P2P\_survey.], [P2P\_file\_sharing]). Consequently, it becomes increasingly important to complement the ALTO effort and reduce upload access traffic, in addition to cross-domain and backbone traffic.

The IETF Low Extra Delay Background Transport (LEDBAT) Working Group is focusing on techniques that allow large amounts of data to be consistently transmitted without substantially affecting the delays experienced by other users and applications. It is expected that some P2P applications would start using such techniques, thereby somewhat alleviating the perceivable impact (at least on other applications) of their high volume traffic. However, such techniques may not be adopted by all P2P applications. Also, when adopted, these techniques do not remove all inefficiencies, such as those associated with traffic being sent upstream as many times as there are remote peers interested in getting the corresponding information. For example, the P2P application transfer completion times remain affected by potentially (relatively) slow upstream transmission. Similarly, the performance of real-time P2P applications may be affected by potentially (relatively) higher upstream latencies.

#### 3.2. P2P cache: a complex in-network storage

An effective technique to reduce P2P infrastructural stress and inefficiency is to introduce in-network storage.

In the current Internet, in-network storage is introduced as P2P caches, either transparently or explicitly as a P2P peer. To provide service to a specific P2P application, the P2P cache server must support the specific signaling and transport protocols of the specific P2P application. This can lead to substantial complexity for the P2P Cache vendor.

First, there are many P2P applications on the Internet (e.g., BitTorrent, eMule, Flashget, and Thunder for file sharing; Abacast, Kontiki, Octoshape, PPLive, PPStream, and UUSee for P2P streaming). Consequently, a P2P cache vendor faces the challenge of supporting a large number of P2P application protocols, leading to product complexity and increased development cost.

Furthermore, a specific P2P application protocol may be evolving continuously, to add new features or fix bugs. This forces a P2P cache vendor to continuously update to track the changes of the P2P application, leading to product complexity, high cost, and low reliability.

Third, many P2P applications use proprietary protocols or support end-to-end encryption. This can render P2P caches ineffective.

## 3.3. Ineffective integration of P2P applications

As P2P applications evolve, it is becoming increasingly clear that they will need in-network resources to provide positive user experiences. For example, multiple P2P streaming systems seek additional in-network resources during a flash crowd, such as just before a major live streaming event. In asymmetric networks when the aggregated upload bandwidth of a channel cannot meet the download demand, a P2P application may seek additional in-network resources to maintain a stable system.

A requirement by some P2P applications in using in-network infrastructural resources, however, is flexibility in implementing resource allocation policies. A major competitive advantage of many successful P2P systems is their substantial expertise in how to most efficiently utilize peer and infrastructural resources. For example, many live P2P systems have specific algorithms to select those peers that behave as stable, higher bandwidth sources. They continue to fine-tune such algorithms. In other words, in-network storage should expose basic mechanisms and allow as much flexibility as possible to P2P applications to implement specific policies. This conforms to the end-to-end systems principle and allows innovation and satisfaction of specific business goals. Existing techniques for P2P application in-network storage lack these capabilities.

#### 4. Motivation

DECADE aims to provide access to storage and data transport services in the network to P2P applications to improve their efficiency and reduce the stress on the network infrastructure. Unlike the existing P2P caching architecture, DECADE aims to provide a standard interface for various P2P applications (both content publishers and end users) to access in-network storage. This decoupling of P2P data access from P2P application control and signaling reduces the complexity of in-network storage services. Furthermore, DECADE is aimed to provide basic access mechanisms and allows P2P applications to implement flexible policies to create an ecosystem for application innovation and various business goals. Besides that, it also improves the availability of P2P contents because the in-network storage is always-on.

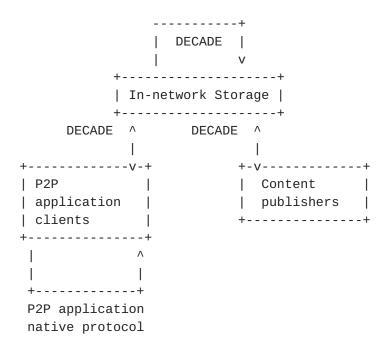

Figure 1 Overview

#### 5. Usage Scenarios

Usage scenarios are presented to illustrate how DECADE in-network storage may be used in both CDN and P2P scenarios. Interactions with in-network storage are described at an abstract level so as not to constrain future protocol development.

#### 5.1. BitTorrent

BitTorrent may be integrated with DECADE to be more network efficient and reduce the bandwidth consumed on ISP networks. When a BitTorrent client uploads a block to peers, the block traverses the last-mile uplink once for each peer. With DECADE, however, the BitTorrent client may upload the block to its in-network storage. Peers may retrieve the block from the in-network storage, reducing the amount of data on the last-mile uplink.

We now describe in more detail how BitTorrent can utilize DECADE. For illustration, we assume that both the BitTorrent client (A) and its peer (B) utilize in-network storage. When A requests a block, peer B replies with a 'redirect' message indicating that the content should be retrieved from in-network storage. If the peer B had not previously stored the content in in-network storage, it uploads the block before A retrieves it. If there is support, A may first copy the block to in-network storage that is nearer to it before retrieving it.

Note that this requires extensions to the BitTorrent protocol. While there are multiple ways to do so, this example assumes the native BitTorrent 'request' message is extended to carry additional information and that a new 'redirect' message is added. Upload and download to/from in-network storage uses a standard protocol.

This example has illustrated how utilizing DECADE can increase BitTorrent's network efficiency. First, notice that peer B does not utilize any uplink bandwidth if the block was already present in its in-network storage. Second, notice that the block may be copied to in-network storage nearer to A. When A wishes to share the block with another peer (say, peer C) that supports DECADE, it may upload directly from its in-network storage, again avoiding usage of the last-mile uplink.

This technique can be applied to other P2P applications as well. Since P2P applications use a standard for communicating with innetwork storage, they no longer require in-network storage to explicitly support their protocol. P2P applications retain the ability to explicitly manage which content is placed in in-network storage, as well as access and resource control polices.

## 5.2. Content Publisher

Content Publishers may also utilize in-network storage. For example, consider a P2P live streaming application. A Content Publisher typically maintains a small number of sources, each of which distributes blocks in the current play buffer to a set of the P2P

peers.

Consider a case where the Content Publisher owns an in-network storage account within ISP A. If there are multiple P2P peers within ISP A, the Content Publisher may utilize DECADE to distribute content to the peers.

First, the Content Publisher stores a block in the in-network storage, configures necessary access control, and notifies peers in ISP A. Second, each peer may then download from the Content Publisher's in-network storage.

In this example, the block is distributed in a more network efficient way (the content only traverses the ISP's interdomain link once), while the Content Publisher retains explicit control over access to the content placed in its own storage. The Content Publisher can remove content from its in-network storage when it is stale or needs to be replaced, and grant access and resources to only the desired peers.

Note that Content Publishers and individual peers can each use innetwork storage. For example, after downloading content from the Content Publisher's in-network storage, peers may each utilize their own in-networks storage similar to the usage scenario in <a href="Section 5.1">Section 5.1</a>. This can have the benefit of increased network efficiency, while Content Publishers and peers still retain control over content placed in their own in-network storage.

If it desires, a content publisher may still apply DRM to the payload. This is independent of any authentication or authorization provided by DECADE.

# 5.3. CDN/P2P hybrid

Some applications use a hybrid content distribution approach incorporating both P2P and CDN modes. As an example, Internet TV may be implemented as a hybrid CDN/P2P application by distributing content from central servers via a CDN, and also incorporating a P2P mode amongst endhosts and set-top boxes.

DECADE may be beneficial to hybrid CDN/P2P applications as well. However, if only the endhost can store content in the DECADE server, the content must be downloaded and then uploaded over the last-mile access link before another peer may retrieve it from a DECADE server. Thus, in this deployment scenario, it may be advantageous for a Content Publisher or CDN provider to store content to DECADE servers.

## **6**. Security Considerations

There are multiple security considerations. We can not enumerate all of them but focus on three main concerns in this section.

#### 6.1. Denial of Service Attacks

An attacker can try to consume a large portion of the in-network storage, or exhaust the connections of the in-network storage through a Denial of Service (DoS) attack.

#### 6.2. Copyright and Legal Issues

Copyright and other laws may prevent the distribution of certain content in various localities. While in-network storage operators may adopt system-wide ingress or egress filters to implement necessary policies for storing or retrieving content, and applications may still apply DRM to the data stored in the network storage, the specification and implementation of such policies (e.g., filtering and DRM) is outside of the scope of this working group.

#### 6.3. Privacy issue

If the content stored in the provider-based in-network storage, there may be a privacy risk that the provider can correlate the people who are accessing the same data object using the same object identity.

#### 7. IANA Considerations

There are no IANA considerations in this document.

## Appendix A. Other Related Work in IETF

Note that DECADE is independent of current IETF work on P2P. The ALTO work as described above is aimed for better peer selection and the RELOAD [I-D.ietf-p2psip-base] protocol is used for P2P overlay maintenance and resource discovery.

The Peer to Peer Streaming Protocol effort in the IETF is investigating the specification of signaling protocols (called the PPSP tracker protocol and peer protocol) for multiple entities (e.g. intelligent endpoints, caches, content distribution network nodes, and/or other edge devices) to participate in P2P streaming systems in both fixed and mobile Internet. As discussed in the PPSP problem statement, one important PPSP use case is the support of an innetwork edge cache for P2P Streaming. However, this approach to providing in-network cache has different applicability, different objectives and different implications for the in-network cache operator. A DECADE service can be used for any application transparently to the DECADE in-network storage operator: it can be used for any P2P Streaming application (whether it supports PPSP protocols or not), for any other P2P application, and for non P2P applications that simply want to benefit from in-network storage. with DECADE the operator is providing a generic in-network storage service that can be used by any application without application involvement or awareness by the operator; in the PPSP cache use case, the cache operator is participating in the specific P2P streaming service.

DECADE and PPSP can both contribute independently, and (where appropriate) simultaneously, to making content available closer to peers. Here are a number of example scenarios:

A given network supports DECADE in-network storage, and its CDN nodes do not participate as PPSP Peers for a given "stream" (e.g. because no CDN arrangement has been put in place between the Content Provider and the particular network provider). In that case, PPSP Peers will all be "off-net" but will be able to use DECADE in-network storage to exchange chunks.

A given network does not support DECADE in-network storage, and (some of) its CDN nodes participate as PPSP Peers for a given "stream" (e.g. say because an arrangement has been put in place between the Content Provider and the particular network provider). In that case, the CDN nodes will participate as in-network PPSP

Peers. The off-net PPSP Peers (i.e., end users) will be able to get chunks from the in-network CDN nodes (using PPSP protocols with the CDN nodes).

A given network supports DECADE in-network storage, and (some of) its CDN nodes participate as PPSP Peers for a given "stream" (e.g. say because an arrangement has been put in place between the Content Provider and the particular network provider). In that case, the CDN nodes will participate as in-network PPSP Peers. The off-net PPSP Peers (i.e., end users) will be able to get chunks from the in-network CDN nodes (using PPSP protocols with the CDN nodes) as well as be able to get chunks / share chunks using DECADE in-network storage populated by PPSP Peers (both off-net end-users and in-network CDN Nodes).

PPSP and DECADE jointly to provide P2P streaming service for heterogeneous networks including both fixed and mobile connections and enables the mobile nodes to use DECADE. In this case there may be some solutions to require more information in PPSP tracker protocol, e.g., the mobile node can indicate its DECADE in-network proxy to PPSP tracker and the following requesting peer can finish data transfer with the DECADE proxy.
