YANG Data Model for DHCPv6 Configuration
draft-ietf-dhc-dhcpv6-yang-14

Abstract

This document describes YANG data modules for the configuration and management of DHCPv6 servers, relays, and clients.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#) [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 17 June 2021.

[Page 2]

1. Introduction

DHCPv6 [[RFC8415](#)] is widely used for supplying configuration and other relevant parameters to clients in IPv6 networks. This document defines YANG modules for the configuration and management of DHCPv6 servers, relays and clients. Separate 'element' modules are defined for each of these. There is an additional module per-element defining DHCP options which are relevant for that element (taken from the options defined in [[RFC8415](#)]).

Additionally, a 'common' module contains typedefs and groupings used by all of the element modules.

It is worth noting that as DHCPv6 is itself a client configuration protocol, it is not the intention of this document to provide a replacement for the allocation of DHCPv6 assigned addressing and parameters by using NETCONF/YANG. The DHCPv6 client module is intended for the configuration and monitoring of the DHCPv6 client function and does not play a part in the normal DHCPv6 message flow.

1.1. Scope

[[RFC8415](#)] describes the current version of the DHCPv6 base protocol specification. A large number of additional specifications have also been published, extending DHCPv6 element functionality and adding new options. The YANG modules contained in this document do not attempt to capture all of these extensions and additions, rather to model the DHCPv6 functions and options covered in [[RFC8415](#)]. A focus has also been given on the extensibility of the modules so that it is easy to augment in additional functionality as required by a particular implementation or deployment scenario.

1.2. Extensibility of the DHCPv6 Server YANG Module

The modules in this document only attempt to model DHCPv6 specific behavior and do not cover the configuration and management of functionality relevant for specific server implementations. The level of variance between implementations is too great to attempt to standardize in a way that is useful without being restrictive.

However, it is recognized that implementation specific configuration and management is also an essential part of DHCP deployment and operations. To resolve this, [Appendix B](#) contains an example YANG module for the configuration of implementation specific functions, illustrating how this functionality can be augmented into the main 'ietf-dhcpv6-server.yang' module.

In DHCPv6 the concept of 'class selection' for messages received by the server is common. This is the identification and classification of messages based on a number of parameters so that the correct provisioning information can be supplied. For example, allocating a prefix from the correct pool, or supplying a set of options relevant for a specific vendor's client implementation. During the development of this document, research has been carried out into a number of vendor's class selection implementations and the findings were that while this function is common to all, the method for configuring and implementing this function differs greatly. Therefore, configuration of the class selection function has been omitted from the DHCPv6 server module to allow implementors to define their own suitable YANG module. [Appendix C](#) provides an example of this, to demonstrate how this is can be integrated with the main 'ietf-dhcpv6-server.yang' module.

1.2.1. DHCPv6 Option Definitions

A large number of DHCPv6 options have been created in addition to those defined in [[RFC8415](#)]. As implementations differ widely in which DHCPv6 options that they support, the following approach has been taken to defining options: Only the DHCPv6 options defined in [[RFC8415](#)] are included in this document.

Of these, only the options that require operator configuration are modelled. E.g. OPTION_IA_NA (3) is created by the DHCP server when requested by the client. The contents of the fields in the option are based on a number of input configuration parameters which the server will apply when it receives the request (e.g., the T1/T2 timers that are relevant for the pool of addresses). As a result, there are no fields that are directly configurable in the option, so it is not modelled.

Further options definitions can be added by additional YANG modules via augmentation into the relevant element modules from this document. [Appendix A](#) contains an example module showing how the DHCPv6 option definitions can be extended in this manner. Some guidance on how to write YANG modules for additional DHCPv6 options is also provided.

1.3. Terminology

The reader should be familiar with the YANG data modelling language defined in [[RFC7950](#)].

The YANG modules in this document adopt the Network Management Datastore Architecture (NMDA) [[RFC8342](#)]. The meanings of the symbols used in tree diagrams are defined in [[RFC8340](#)].

Figure 1: DHCPv6 Server Data Module Structure

Descriptions of important nodes:

- * **dhcpv6-node-type**: The different functional DHCPv6 elements each have their relevant identities.
- * **dhcpv6-server**: This container holds the server's DHCPv6 specific configuration.
- * **server-duid**: Each server must have a DUID (DHCP Unique Identifier) to identify itself to clients. A DUID consists of a two-octet type field and an arbitrary length (of no more than 128-bytes) content field. Currently there are four defined types of DUIDs in [RFC8415] and [RFC6355]: DUID-LLT, DUID-EN, DUID-LL, and DUID-UUID. DUID-Unknown is used for arbitrary DUID formats which do not follow any of these defined types. 'active-duid' is a read-only field that the server's current DUID can be retrieved from. The DUID definitions are imported from the 'ietf-dhcpv6-common.yang' module.
- * **vendor-config**: This container is provided as a location for additional implementation specific YANG nodes for the configuration of the device to be augmented. See [Appendix B](#) for an example of such a module.

- * option-sets: The server can be configured with multiple option-sets. These are groups of DHCPv6 options with common parameters which will be supplied to clients on request. The 'option-set-id' field is used to reference an option-set elsewhere in the server's configuration.
- * option-set: Holds configuration parameters for DHCPv6 options. The initial set of definitions are contained in the module 'ietf-dhcpv6-options-rfc8415-server.yang' and are augmented into the server module at this point. Other DHCPv6 option modules can be augmented here as required.
- * class-selector: This is provided as a location for additional implementation specific YANG nodes for vendor specific class selector nodes to be augmented. See [Appendix C](#) for an example of this.
- * network-ranges: This module uses a hierarchical model for the allocation of addresses and prefixes. At the top level 'network-ranges' holds global configuration parameters. Under this, a list of 'network-ranges' can be defined. Inside 'network-ranges', 'address-pools' (for IA_NA and IA_TA allocations), and 'prefix-pools' (for IA_PD allocation) are defined. Finally within the pools, specific host-reservations are held.
- * prefix-pools: Defines pools to be used for prefix delegation to clients. As prefix delegation is not supported by all DHCPv6 server implementations, it is enabled by a feature statement.

Information about notifications:

- * address/prefix-pool-utilization-threshold-exceeded: Raised when number of leased addresses or prefixes exceeds the configured usage threshold.
- * invalid-client-detected: Raised when the server detects an invalid client. A description of the error that has generated the notification can be included.
- * decline-received: Raised when a DHCPv6 Decline message is received from a client.
- * non-success-code-sent: Raised when a status message is raised for an error.

Information about RPCs

- * delete-address-lease: Allows the deletion of a lease for an individual IPv6 address from the server's lease database.
- * delete-prefix-lease: Allows the deletion of a lease for an individual IPv6 prefix from the server's lease database.

[2.2. DHCPv6 Relay Tree Diagram](#)

The tree diagram in Figure 2 provides an overview of the DHCPv6 relay module. The tree also includes the augmentations of the relevant option definitions from [Section 3.5](#) and the common functions module [Section 3.7](#).

Figure 2: DHCPv6 Relay Data Module Structure

Descriptions of important nodes:

- * **dhcpv6-node-type**: The different functional DHCPv6 elements each have their relevant identities.
- * **dhcpv6-relay**: This container holds the relay's DHCPv6 specific configuration.
- * **relay-if**: As a relay may have multiple client-facing interfaces, they are configured in a list. The if-name leaf is the key and is an interface-ref to the applicable interface defined by the 'ietf-interfaces' YANG module.
- * **destination-addresses**: Defines a list of IPv6 addresses that client messages will be relayed to. May include unicast or multicast addresses.
- * **link-address**: Configures the value that the relay will put into the link-address field of Relay-Forward messages.

- * prefix-delegation: As prefix delegation is not supported by all DHCPv6 relay implementations, it is enabled by this feature statement where required.
- * pd-leases: Contains read-only nodes for holding information about active delegated prefix leases.
- * relay-options: As with the Server module, DHCPv6 options that can be sent by the relay are augmented here.

Information about notifications:

- * topology-changed: Raised when the topology of the relay agent is changed, e.g. a client facing interface is reconfigured.

Information about RPCs

- * clear-prefix-lease: Allows the removal of a delegated lease entry from the relay.
- * clear-client-prefixes: Allows the removal of all of the delegated lease entries for a single client (referenced by client DUID) from the relay.
- * clear-interface-prefixes: Allows the removal of all of the delegated lease entries from an interface on the relay.

[2.3. DHCPv6 Client Tree Diagram](#)

The tree diagram in Figure 3 provides an overview of the DHCPv6 client module. The tree also includes the augmentations of the relevant option definitions from [Section 3.6](#) and the common functions module [Section 3.7](#).

```

Figure 3: DHCPv6 Client Data Module Structure

Descriptions of important nodes:

- * **dhcpv6-node-type**: The different functional DHCPv6 elements each have their relevant identities.
- * **dhcpv6-client**: This container holds the client's DHCPv6 specific configuration.

- * client-if: As a client may have multiple interfaces requesting configuration over DHCP, they are configured in a list. The if-name leaf is the key and is an interface-ref to the applicable interface defined by the 'ietf-interfaces' YANG module.
- * client-duid: Each DHCP client must have a DUID (DHCP Unique Identifier) to identify itself to clients. A DUID consists of a two-octet type field and an arbitrary length (of no more than 128-bytes) content field. Currently there are four defined types of DUIDs in [[RFC8415](#)]: DUID-LLT, DUID-EN, DUID-LL, and DUID-UUID. DUID-Unknown is used for arbitrary DUID formats which do not follow any of these defined types. 'active-duid' is a read-only field that the client's current DUID can be retrieved from. The DUID definitions are imported from the 'ietf-dhcpv6-common.yang' module. DUID is configured under the 'client-if' to allow a client to have different DUIDs for each interface if required.
- * ia-na, ia-ta, ia-pd: Contains configuration nodes relevant for requesting one or more of each of the lease types. Also contains read only nodes related to active leases.

Information about notifications:

- * invalid-ia-detected: Raised when the identity association of the client can be proved to be invalid. Possible conditions include: duplicated address, illegal address, etc.
- * retransmission-failed: Raised when the retransmission mechanism defined in [[RFC8415](#)] has failed.

3. DHCPv6 YANG Modules

3.1. DHCPv6 Server YANG Module

This module imports typedefs from [[RFC6991](#)], [[RFC8343](#)].

```
<CODE BEGINS> file "ietf-dhcpv6-server.yang"

module ietf-dhcpv6-server {

[4. Security Considerations](#)

The YANG modules defined in this document are designed to be accessed via network management protocols such as NETCONF [[RFC6241](#)] or RESTCONF [[RFC8040](#)]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [[RFC6242](#)]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [[RFC8446](#)].

The Network Configuration Access Control Model (NACM) [[RFC8341](#)] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

All data nodes defined in the YANG modules which can be created, modified, and deleted (i.e., config true, which is the default) are considered sensitive. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations.

As the RPCs for deleting/clearing active address and prefix entries in the server and relay modules are particularly sensitive, these use 'nacm:default-deny-all'.

An attacker who is able to access the DHCPv6 server can undertake various attacks, such as:

- * Denial of service attacks, based on re-configuring messages to a rogue DHCPv6 server.
- * Various attacks based on re-configuring the contents of DHCPv6 options. E.g., changing the address of a the DNS server supplied in a DHCP option to point to a rogue server.

An attacker who is able to access the DHCPv6 relay can undertake various attacks, such as:

- * Re-configuring the relay's destination address to send messages to a rogue DHCPv6 server.
- * Deleting information about a client's delegated prefix, causing a denial of service attack as traffic will no longer be routed to the client.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These subtrees and data nodes can be misused to track the activity of a host:

- * Re-configuring the relay's destination address to send messages to a rogue DHCPv6 server.
- * Information the server holds about clients with active leases: (dhcpv6-server/network-ranges/network-range/ address-pools/ address-pool/active-leases)
- * Information the relay holds about clients with active leases: (dhcpv6-relay/relay-if/prefix-delegation/)

Security considerations related to DHCPv6 are discussed in [[RFC8415](#)].

Security considerations given in [[RFC7950](#)] are also applicable here.

5. IANA Considerations

This document registers the following YANG modules in the "YANG Module Names" registry [[RFC6020](#)].

name:	ietf-dhcpv6
namespace:	urn:ietf:params:xml:ns:yang:ietf-dhcpv6-common
prefix:	dhcpv6

```
reference:      TBD

name:          ietf-dhcpv6

Appendix A. Example of Augmenting Additional DHCPv6 Option Definitions

The following section provides a example of how the DHCPv6 option definitions can be extended for additional options. It is expected that additional specification documents will be published in the future for this.

The example defines YANG models for OPTION_SIP_SERVER_D (21) and OPTION_SIP_SERVER_D (22) defined in [RFC3319]. The overall structure is as follows:

- * A separate grouping is used for each option.
- * The name of the option is taken from the registered IANA name for the option, with an '-option' suffix added.
- * The description field is taken from the relevant option code name and number.
- * The reference section is the number and name of the RFC in which the DHCPv6 option is defined.
- * The remaining fields match the fields in the DHCP option. They are in the same order as defined in the DHCP option. Where-ever possible, the format that is defined for the DHCP field should be matched by the relevant YANG type.
- * Fields which can have multiple entries or instances are defined using list or leaf-list nodes.

Below the groupings for option definitions, augment statements are used to add the option definitions for use in the relevant DHCP element's module (server, relay and/or client). If an option is relevant to more than one element type, then an augment statement for each element is used.

uses sip-server-address-list-option-group;
}
}

<CODE ENDS>
```

The correct location to augment the new option definition(s) will vary according to the specific rules defined for the use of that specific option. E.g. for options which will be augmented into the ietf-dhcpv6-server module, in many cases, these will be augmented to:

```
'/dhcpv6-server:dhcpv6-server/dhcpv6-server:option-sets/\ dhcpv6-server:option-set'
```

so that they can be defined within option sets. However, there are some options which are only applicable for specific deployment scenarios and in these cases it may be more logical to augment the option group to a location relevant for the option.

One example for this could be OPTION_PD_EXCLUDE (67). This option is only relevant in combination with a delegated prefix which contains a specific prefix. In this case, the following location for the augmentation may be more suitable:

```
'/dhcpv6-server:dhcpv6-server/dhcpv6-server:network-ranges/\ dhcpv6-
server:network-range/dhcpv6-server:prefix-pools/\ dhcpv6-
server:prefix-pool"
```

Appendix B. Example Vendor Specific Server Configuration Module

This section shows how to extend the server YANG module defined in this document with vendor specific configuration nodes, e.g., configuring access to a lease storage database.

The example module defines additional server attributes such as name and description. Storage for leases is configured using a lease-storage container. It allows storing leases in one of three options: memory (memfile), MySQL and PosgreSQL. For each case, the necessary configuration parameters are provided.

At the end there is an augment statement which adds the vendor specific configuration defined in "dhcpv6-server-config:config" under '/dhcpv6-server:config/dhcpv6-server:vendor-config' mount point.

Appendix C. Example definition of class selector configuration

The module "ietf-example-dhcpv6-class-selector" provides an example of how vendor specific class selection configuration can be modelled and integrated with the "ietf-dhcpv6-server" module defined in this document.

The example module defines "client-class-names" with associated matching rules. A client can be classified based on "client-id", "interface-id" (ingress interface of the client's messages), packets source or destination address, relay link address, relay link interface-id and more. Actually, there are endless methods for classifying clients. So this standard does not try to provide full specification for class selection, it only shows an example how it can be defined.

At the end of the example augment statements are used to add the defined class selector rules into the overall DHCPv6 addressing hierarchy. This is done in two main parts:

- * The augmented class-selector configuration in the main DHCPv6 Server configuration.
- * client-class leafrefs augmented to "network-range", "address-pool" and "pd-pool", pointing to the "client-class-name" that is required.

The mechanism is as follows: class is associated to client based on rules and then client is allowed to get address(es)/prefix(es) from given network-range/pool if the class name matches.
