Abstract

A node may have support for communications using IPv4 and/or IPv6 protocols. Such a node may wish to obtain IPv4 and/or IPv6 configuration settings via the Dynamic Host Configuration Protocol (DHCP). The original version of DHCP [1] designed for IPv4 has now been complemented by a new DHCPv6 [4] for IPv6. This document describes issues identified with dual IP version DHCP interactions,

Internet-Draft DHCP: Dual-Stack Issues July 2004

[1.](#) Introduction

The original specification of the Dynamic Host Configuration Protocol (DHCP) was made with only IPv4 in mind. That specification has been subsequently revised, up to the latest version of DHCP [[1](#)]. With the arrival of IPv6, a new DHCP specification for IPv6 has been designed, and published as DHCPv6 [[4](#)].

These protocols allow nodes to communicate via IPv4 or IPv6 to retrieve configuration settings for operation in a managed environment. While an IPv6 node may acquire address-related configuration settings via IPv6 stateless address autoconfiguration [[2](#)], such a node may wish to use stateless DHCPv6 [[5](#)] for other administratively configured options (e.g. DNS, NTP).

In early IPv6 deployments, a dual-stack mode of operation is typically used. There will thus be nodes that require both IPv4 and IPv6 configuration settings. This document discusses issues with obtaining such settings in a dual-stack environment.

In this document, we refer to a "DHCP server" as a server implementing the original DHCP [1], and a "DHCPv6 server" as a server implementing DHCPv6 [4] or its stateless subset [5].

2. Configuration scenarios

For a node in an IPv4-only or IPv6-only environment, the choice of DHCP server is a straightforward one; a DHCP server for IPv4, or a DHCPv6 server for IPv6.

In a dual-stack environment a node in a managed environment will need to obtain both IPv4 and IPv6 configuration settings, e.g.

- o IPv4 address

- o IPv6 address

- o NTP server

- o DNS server

- o NIS server

- o DNS search path

While the format of address settings will be IP-specific, the node may equally well acquire IPv4 or IPv6 addresses for some settings, e.g. for DNS or NTP, if those services are available via IPv4 or

IPv6 transport. Currently, a DHCP server returns IPv4 data, while a DHCPv6 server returns IPv6 data.

It is worth noting that in an IPv4 environment, with a DHCP server, the choice of whether to use DHCP is made by the node. In an IPv6 environment, the use of the managed and other bits in the Router Advertisement can offer a hint to the node whether or not to use full DHCPv6 or its stateless variant. It is perhaps not clear whether a dual-stack node should do DHCP for IPv4 if Managed and OtherConfig flags in the Router Advertisement are both off; it seems most appropriate that the decision to use DHCP for IPv4 or not should be as if the host was IPv4-only.

3. Dual-stack issues

In this section we list issues that have been raised to date related to dual-stack DHCP operation.

It has been noted from comments that the first four, and possibly five, subsections here may also be viewed as multihoming issues.

3.1 Handling multiple responses

The general question is how to handle configuration information that may be gathered from multiple sources. Where those sources are DHCP and DHCPv6 servers (which may be two physical nodes or two servers running on the same node) the client node needs to know whether to use the most recent data, or whether to perform some merger or union of the responses by certain rules. A node may choose to ask a DHCPv6 server and only use a DHCP server if no response is received.

Merging is possible, but is likely to be complex. There could be some priority, so that if both DHCP and DHCPv6 servers offer a value, only one is used. Or the node could choose to store and use both, in some order of its choosing.

A node may also obtain information from other sources, e.g. a manual configuration file (e.g. `/etc/resolv.conf` for DNS data on many Unix

systems). A node configured manually to use an IPv6 DNS server via such manual configuration may lose that configuration if it then uses DHCP to obtain IPv4 settings if in a dual-stack environment; that IPv4 configuration may then overwrite the manual IPv6 DNS setting with new IPv4 settings from the DHCP response.

[3.2](#) Different administrative management

In some deployments, the IPv4 and IPv6 services may not be administered by the same organisation or people, e.g. in a community

Chown, et al. Expires January 17, 2005 [Page 4]

Internet-Draft DHCP: Dual-Stack Issues July 2004

wireless environment. This poses problems for consistency of data offered by either DHCP version.

[3.3](#) Multiple interfaces

A node may have multiple interfaces and run IPv4 and IPv6 on different interfaces. A question then is whether the settings are per interface or per node? DHCPv6 introduces the idea of a DHCP Unique Identifier (DUID) which does not yet exist for DHCP; some effort is being made to retrofit the concept to DHCPv4 [6].

Per interface settings can be complex because a client node needs to know from which interface system settings like NTP server came from. And it may not be apparent which setting should be used, if e.g. an NTP server option is received on multiple interfaces, potentially over different protocols.

[3.4](#) DNS load balancing

In some cases it is preferable to list DNS server information in an ordered way per node for load balancing, giving different responses to different clients. Responses from different DHCP and DHCPv6

servers may make such configuration problematic.

[3.5](#) DNS search path issues

The DNS search path may vary for administrative reasons. For example, a site under the domain foo.com chooses to place an early IPv6 deployment under the subdomain ipv6.foo.com, until it is confident of offering a full dual-stack service under its main domain. The subtlety here is that the DNS search path then affects choice of protocol used, e.g. IPv6 for nodes in ipv6.foo.com.

[3.6](#) Protocol startup sequence

In the dual-stack environment, one needs to consider what happens if, for example, the IPv6 interface (transport) is started after DHCPv4 was used to configure the client. Should the client then simply discard the current IPv4 information, or merge it with a subsequent IPv6 response?

[3.7](#) DHCP option variations

Some options in DHCP are not available in DHCPv6 and vice-versa. Some IP-version limitations naturally apply, e.g. only IPv6 addresses can be in an IPv6 NTP option. The DHCP and DHCPv6 option numbers may be different.

There may be some sites that would choose to use IPv4-mapped addresses in DHCPv6-based options. The merits and drawbacks of such an approach need discussion.

A site administrator may wish to configure all their dual-stack nodes with (say) two NTP servers, one of which has an IPv4 address, the

other an IPv6 address. In this case it may be desirable for an NTP option to carry a list of addresses, where some may be IPv4 and some may be IPv6. In general one could consider having DHCPv6 options that can carry mix of IPv4 and IPv6 addresses.

[3.8](#) Security issues

At this stage in the formation of this draft no specific security issues have been raised. The authors welcome comments on this, should such issues exist.

While there is a specification for authentication for DHCP messages [3], the standard seems to have very few, if any, implementations. Thus DHCP and DHCPv6 servers are still liable to be spoofed. Adding an additional protocol may give an extra avenue for attack, should an attacker perhaps spoof a DHCPv6 server but not a DHCP server.

[4.](#) Potential solutions

While this document did not originally intend to have solutions in its scope, we discuss potential solution spaces in brief here in order to provoke some discussion of the issues. If separate solution document(s) emerge, these notes may be removed from this document; alternatively this document could be expanded to become a best practice guide. Comments on this are welcomed.

[4.1](#) Separate DHCP servers

One solution is to run separate DHCP and DHCPv6 servers. These may or may not be run on the same physical node. The information served from the DHCP servers could be generated from a single database instance for consistency.

In this approach, some best practice guidance is required for how multiple responses are handled or merged. Administrators have the onus to maintain consistency (e.g. scripts may generate common DHCP and DHCPv6 configuration files).

In some cases, inconsistencies may not matter. In a simple case, an NTP server will give the same time whether accessed by IPv4 or IPv6. Even if different recursive DNS servers are offered via DHCP or DHCPv6, those name servers will provide the same response to a given

query. The order of DNS servers in a node's configuration is not important, unless DNS load balancing is required.

In other cases, inconsistencies may be an issue, e.g. where lists of values are returned, an algorithm is needed for list merger (e.g. "alternate, DHCPv6 first"). Or there may be incompatible configuration values where, for example, DHCPv6 supplies domain names (such the SMTP or POP servers) whereas DHCPv4 provided only IPv4 addresses.

In the case of separate servers, there are some options like DNS search path, that aren't used in a specific IP protocol context.

The multiple server approach will have some simplifications. The DHCPv4 and DHCPv6 servers may provide the same value for a particular parameter, in which case there is no conflict. In some cases the value may be different, but the effect should be the same (e.g. NTP server). The crux of the issue is to identify where differences may occur and where these differences will have an impact on node behaviour.

One possible solution is to have per-host preferences, or an ordered list of preferences, e.g. "use manually configured", "prefer DHCPv4", or "prefer DHCPv6", assuming the host can act based upon which protocol is used. It is then up to the site administrator to ensure values returned from either DHCP are consistent (a principle which extends if other methods are used, e.g. NIS or SLP).

[4.2](#) Single DHCPv6 server

There is an argument for not having to configure and operate both DHCP and DHCPv6 servers in a dual-stack site environment. The use of both servers may also lead to some redundancy in the information

served. Thus one solution may be to modify DHCPv6 to be able to return IPv4 information. This solution is hinted at in the DHCPv6 [4] specification: "If there is sufficient interest and demand, integration can be specified in a document that extends DHCPv6 to carry IPv4 addresses and configuration information." This solution may allow DHCP for IPv4 to be completely replaced by DHCPv6 with additional IPv4 information options, for dual-stack nodes.

A general argument is that which DHCP protocol is used (whether it's over IPv4 or IPv6) shouldn't affect what kind of addresses you can get configured with it, and that simplicity and predicatability comes from using a single server over a single transport. IPv4-capable hosts will likely remain for at least 10 years, probably much longer; do we want dual-stack hosts (which will become the norm) to do both DHCPv4 and DHCPv6 forever while dual-stack? If you need both servers

Chown, et al.

[Page 7]

Internet-Draft

DHCP: Dual-Stack Issues

July 2004

to configure interfaces with addresses, and get other configuration, then you rely on two separate protocols to work (servers and relays, etc) in order for the host to behave correctly.

This approach may require the listing of a mix of IPv4 and IPv6 addresses for an option. This should be considered when new IPv6 options are introduced. There could be just two options needed, one new option for the address delegation, and one for doing encapsulation.

Also, there are a number of paradigms in DHCPv6 that we miss in DHCPv4, e.g. going away from using MAC addresses for per-host address assignment but instead using DUIDs/IAIDs, etc (although there is ongoing work to provide DUIDs for DHCPv4 [6]).

However, there are a number of potential problems with this approach:

- o IPv4-only nodes would not have any DHCP service available to them; such an approach is only possible in a fully dual-stack

environment.

- o The client node may then be IPv6-only and receiving IPv4 configuration settings that it does not want or be able to meaningfully handle.
- o The DHCPv4 servers need to be configured anyway to support IPv4-only hosts, so there is still duplication of information.
- o What happens if there are DHCPv6 servers that don't return IPv4 information? Does this mean the client can't run IPv4 (since it won't do DHCPv4)?
- o If IPv4 information is served from a DHCPv6 server as well as an IPv4 DHCP server, IPv4 address space will need to be allocated to both servers, fragmenting the potentially precious IPv4 global address resource for the site.

[4.3](#) Administrative and other areas

There are also administrative issues or best practice that could be promoted. For example, it may be recommended that sites do not split their DNS name space for IPv6-specific testbeds.

It may be worth considering whether separate manual configuration files should be kept for IPv4 and IPv6 settings, e.g. separate /etc/resolv.conf files for DNS settings on Unix systems. However, this seems a complex solution that should be better solved by other more

generalised methods.

Some differences in DHCP and DHCPv6 may not be reconciled, but may not need to be, e.g. different ways to assign addresses by DUID in DHCPv6, or the non-aligned option numbers for DHCP and DHCPv6.

5. Summary

There are a number of issues in the operation of DHCP and DHCPv6 servers for nodes in dual-stack environments that should be clarified. While some differences in the protocols may not be reconciled, there may not be a need to do so. However, for general operation some best practice should be agreed, the principle choice being whether separate DHCP and DHCPv6 servers should be maintained by a site, or whether DHCPv6 should be extended to carry IPv4 configuration settings for dual-stack nodes.

It can certainly be argued that until a site is completely dual-stack, an IPv4 DHCP service will always be required (e.g. while there are still legacy printers, IP webcams or devices which still configure via DHCPv4), and a single IPv6 transport DHCP server offering configuration information for both protocols will then not be sufficient. In that case, there is a good rationale for focusing effort on how to combine the information received from separate IPv4 DHCP and (stateless) DHCPv6 servers.

In theory, it should be relatively straightforward to write a configuration manager that would accept a single configuration specification from the service manager and distribute the correct (and consistent) configurations to the DHCPv4 and DHCPv6 servers (whether on the same host or not). In this case, maintaining coordinated configurations in two servers is an interface issue, not a protocol issue. The question then is whether the client has all the information it needs to make reasonable choices. We are aware of one implementation of separate DHCPv4 and DHCPv6 clients that is using a preference option for assisting client-side merging of the received information.

Another issue for discussion is whether a combined DHCP service only available over IPv6 transport is a desirable longer-term goal for networks containing only dual-stack or IPv6-only nodes (or IPv4-only nodes where DHCPv4 is not needed). The transition to the long-term position may easily take more than 10 years.

This work has overlap with multihoming and multi-interface configuration issues. It is also interwoven with the Detecting Network Attachment area, e.g. where a node may move from an

IPv4-only network to a dual-stack network, or vice versa. Both

Chown, et al.

[Page 9]

Internet-Draft

DHCP: Dual-Stack Issues

July 2004

aspects may be best abstracted for discussion in the IETF multi6 and dna WGs for discussion.

The authors also noted that the original working title of the draft was not as appropriate as it might be; we have thus renamed it "DHCP: IPv4 and IPv6 Dual-Stack Issues". We are open to further renaming if comments warrant it.

There is not a full consensus in the DHC WG on solutions for the DHCP dual-stack configuration issue at present. This text is intended to provoke discussion towards a consensus, and it may then document that consensus and the reasons behind it for future reference.

[6.](#) Security Considerations

There are no security considerations in this problem statement per se, as it does not propose a new protocol.

[7.](#) Acknowledgements

The authors thank the following people for input to this draft: Bernie Volz, AK Vijayabhaskar, Ted Lemon, Ralph Droms, Robert Elz, Changming Liu, Margaret Wasserman and Greg Daley. The draft may not fully reflect the views of each of these individuals.

The authors would also like to thank colleagues on the 6NET project for contributions to this draft.
