Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations <<u>draft-ietf-disman-remops-mib-08.txt</u>>

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of <u>Section 10 of RFC2026</u>. Internet Drafts are working documents of the Internet Engineering Task Force (IETF), its Areas, and its Working Groups. Note that other groups may also distribute working documents as Internet Drafts.

Internet Drafts are draft documents valid for a maximum of six months. Internet Drafts may be updated, replaced, or obsoleted by other documents at any time. It is not appropriate to use Internet Drafts as reference material or to cite them other than as a "working draft" or "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/ietf/lid-abstracts.txt

The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

Please check the I-D abstract listing contained in each Internet Draft directory to learn the current status of this or any Internet Draft. Distribution of this document is unlimited.

Abstract

This memo defines Management Information Bases (MIBs) for performing remote ping, traceroute and lookup operations at a remote host. When managing a network it is useful to be able to initiate and retrieve the results of ping or traceroute operations when performed at a remote host. A Lookup capability is defined in order to enable resolving of either an IP address to an DNS name or an DNS name to an IP address at a remote host.

DISMAN Working Group Expires September 2000 [Page 1]

Internet Draft

Currently, there are several enterprise-specific MIBs for performing remote ping or traceroute operations. The purpose of this memo is to define a standards-based solution to enable interoperibility.

<u>1.0</u> Introduction

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",

"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>RFC 2119</u>, reference [<u>13</u>].

DISMAN Working Group Expires September 2000 [Page 2]

Internet Draft Ping, Traceroute and Lookup MIBs March 1, 2000

This document is a product of the Distributed Management (DISMAN) Working Group. Its purpose is to define standards-based MIB modules for performing specific remote operations. The remote operations defined by this document consist of the ping, traceroute and lookup functions.

Ping and traceroute are two very useful functions for managing networks. Ping is typically used to determine if a path exists between two hosts while traceroute shows an actual path. Ping is usually implemented using the Internet Control Message Protocol (ICMP) "ECHO" facility. It is also possible to implement a ping capability using alternate methods, some of which are:

o Using the UDP echo port (7), if supported.

This is defined by RFC 862 [2].

o Timing an SNMP query.

o Timing a TCP connect attempt.

In general, almost any request/response flow can be used to generate a round-trip time. Often many of the non-ICMP ECHO facility methods stand a better chance of yielding a good response (not timing out for example) since some routers don't honor Echo Requests (timeout situation) or they are handled at lower priority, hence possibly giving false indications of round trip times.

It must be noted that almost any of the various methods used for generating a round-trip time can be considered a form of system attack when used excessively. Sending a system requests too often can negatively effect its performance. Attempting to connect to what is supposed to be an unused port can be very unpredictable. There are tools that attempt to connect to a range of TCP ports to test that any receiving server can handle erroneous connection attempts.

It also is important to the management application using a remote ping capability to know which method is being used. Different methods will yield different response times since the protocol and resulting processing will be different. It is RECOMMENDED that the ping capability defined within this memo be implemented using the ICMP Echo Facility.

Traceroute is usually implemented by transmitting a series of probe packets with increasing time-to-live values. A probe packet is a UDP datagram encapsulated into an IP packet. Each hop in a path to the target (destination) host rejects the probe packet (probe's TTL too small) until its time-to-live value becomes large enough for the probe to be forwarded. Each hop in a traceroute path returns an ICMP message that is used to discover the hop and to calculate a round trip time. Some systems use ICMP probes (ICMP Echo request packets) instead of UDP ones to implement traceroute. In both cases traceroute relies on the probes being rejected via an ICMP message to discover the hops taken along a path to the final destination. Both probe types, UDP and ICMP,

DISMAN Working Group Expires September 2000 [Page 3]

Internet Draft Ping, Traceroute and Lookup MIBs March 1, 2000

are encapsulated into an IP packet and thus have a TTL field that can be used to cause a path rejection.

Implementations of the remote traceroute capability as defined within this memo SHOULD be done using UDP packets to a (hopefully) unused port. ICMP probes (ICMP Echo Request packets) SHOULD NOT be used. Many PC implementations of traceroute use the ICMP probe method, which they should not, since this implementation method has been known to have a high probability of failure. Intermediate hops become invisible when a router either refuses to send an ICMP TTL expired message in response to an incoming ICMP packet or simply tosses ICMP echo requests altogether.

The behavior of some routers not to return a TTL expired message in response to an ICMP Echo request is due in part to the following text extracted from RFC792 [20]:

"The ICMP messages typically report errors in the processing of datagrams. To avoid the infinite regress of messages about messages etc., no ICMP messages are sent about ICMP messages."

Both ping and traceroute yield round-trip times measured in milliseconds. These times can be used as a rough approximation for network transit time.

The Lookup operation enables the equivalent of either a gethostbyname() or a gethostbyaddr() call being performed at a remote host. The Lookup gethostbyname() capability can be used to determine the symbolic name of a hop in a traceroute path.

Consider the following diagram:

+------L Remote ping, traceroute, Actual ping, traceroute, +----+or Lookup op. +-----+or Lookup op. +---+ |Local|----->|Target| | Host | | Host | | Host| +---+ +---+ +---+ -----+

A local host is the host from which the remote ping, traceroute, or Lookup operation is initiated using an SNMP request. The remote host is a host where the MIBs defined by this memo are implemented that receives the remote operation via SNMP and performs the actual ping, traceroute, or lookup function.

The SNMP Management Framework presently consists of five major components:

DISMAN Working Group Expires September 2000 [Page 4]

Internet Draft Ping, Traceroute and Lookup MIBs March 1, 2000

- o An overall architecture, described in <u>RFC 2571</u> [7].
- Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIv1 and described in RFC 1155 [14], RFC 1212 [15] and RFC 1215 [16]. The second version, called SMIv2, is described in RFC 2578 [3], RFC 2579 [4] and RFC 2580 [5].
- Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in <u>RFC 1157</u> [1]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in <u>RFC 1901</u> [17] and <u>RFC 1906</u> [18]. The third version of the message protocol is called SNMPv3 and described in <u>RFC 1906</u> [18], <u>RFC 2572</u> [8] and <u>RFC 2574</u> [10].
- Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in <u>RFC 1157</u> [1]. A second set of protocol operations and associated PDU formats is described in <u>RFC 1905</u> [6].
- o A set of fundamental applications described in <u>RFC 2573</u> [9] and the view-based access control mechanism described in <u>RFC 2575</u> [11].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies MIB modules that are compliant to the SMIv2. A MIB conforming to the SMIv1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIv2 will be converted into textual descriptions in SMIv1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

3.0 Structure of the MIBs

This document defines three MIB modules:

O DISMAN-PING-MIB

Defines a ping MIB.

O DISMAN-TRACEROUTE-MIB

Defines a traceroute MIB.

O DISMAN-NSLOOKUP-MIB

DISMAN Working Group Expires September 2000 [Page 5]

Provides access to the resolver gethostbyname() and gethostbyaddr() functions at a remote host.

The ping and traceroute MIBs are structured to allow creation of ping or traceroute tests that can be set up to periodically issue a series of operations and generate NOTIFICATIONs to report on test results. Many network administrators have in the past written UNIX shell scripts or command batch files to operate in fashion similar to the functionality provided by the ping and traceroute MIBs defined within this memo. The intent of this document is to acknowledge the importance of these functions and to provide a standards-based solution.

3.1 Ping MIB

The DISMAN-PING-MIB consists of the following components:

- o pingMaxConcurrentRequests
- o pingCtlTable
- o pingResultsTable
- o pingProbeHistoryTable

<u>**3.1.1</u>** pingMaxConcurrentRequests</u>

The object pingMaxConcurrentRequests enables control of the maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

<u>3.1.2</u> pingCtlTable

A remote ping test is started by setting pingCtlAdminStatus to enabled(1). The corresponding pingCtlEntry MUST have been created and its pingCtlRowStatus set to active(1) prior to starting the test. A single SNMP PDU can be used to create and start a remote ping test. Within the PDU, pingCtlTargetAddress should be set to the target host's address (pingCtlTargetAddressType will default to ipv4(1)), pingCtlAdminStatus to enabled(1), and pingCtlRowStatus to createAndGo(4).

The first index element, pingCtlOwnerIndex, is of type SnmpAdminString, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (<u>RFC 2575</u> [11], VACM) and allows a management application to identify its entries. The send index, pingCtlTestName (also an SnmpAdminString), enables the same management application to have multiple requests outstanding.

Using the maximum value for the parameters defined within a pingEntry can result in a single remote ping test taking at most 15 minutes (pingCtlTimeOut times pingCtlProbeCount) plus whatever time it takes to

DISMAN Working Group Expires September 2000 [Page 6]

Ping, Traceroute and Lookup MIBs March 1, 2000 Internet Draft

send the ping request and receive its response over the network from the target host. Use of the defaults for pingCtlTimeOut and pingCtlProbeCount yields a maximum of 3 seconds to perform a "normal" ping test.

A management application can delete an active remote ping request by setting the corresponding pingCtlRowStatus object to destroy(6).

The contents of the pingCtlTable is preserved across reIPLs (Initial Program Loads) of its agent according the values of each of the pingCtlStorageType objects.

3.1.3 pingResultsTable

An entry in the pingResultsTable is created for a corresponding pingCtlEntry once the test defined by this entry is started.

3.1.4 pingProbeHistoryTable

The results of past ping probes can be stored in this table on a per pingCtlEntry basis. This table is initially indexed by pingCtlOwnerIndex and pingCtlTestName in order for the results of a probe to relate to the pingCtlEntry that caused it. The maximum number of entries stored in this table per pingCtlEntry is determined by the value of pingCtlMaxRows.

An implementation of this MIB will remove the oldest entry in the pingProbeHistoryTable to allow the addition of an new entry once the number of rows in the pingProbeHistoryTable reaches the value specified by pingCtlMaxRows. An implementation MUST start assigning pingProbeHistoryIndex values at 1 and wrap after exceeding the maximum possible value as defined by the limit of this object ('ffffffff'h).

3.2 Traceroute MIB

The DISMAN-TRACEROUTE-MIB consists of the following components:

- traceRouteMaxConcurrentRequests 0
- traceRouteCtlTable 0
- 0 traceRouteResultsTable
- traceRouteProbeHistoryTable 0
- 0 traceRouteHopsTable

3.2.1 traceRouteMaxConcurrentRequests

The object traceRouteMaxConcurrentRequests enables control of the

maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit

DISMAN Working Group Expires September 2000 [Page 7]

Ping, Traceroute and Lookup MIBs March 1, 2000 Internet Draft

the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

3.2.2 traceRouteCtlTable

A remote traceroute test is started by setting traceRouteCtlAdminStatus to enabled(1). The corresponding traceRouteCtlEntry MUST have been created and its traceRouteCtlRowStatus set to active(1) prior to starting the test. A single SNMP PDU can be used to create and start a remote traceroute test. Within the PDU, traceRouteCtlTargetAddress should be set to the target host's address (traceRouteCtlTargetAddressType will default to ipv4(1)), traceRouteCtlAdminStatus to enabled(1), and traceRouteCtlRowStatus to createAndGo(4).

The first index element, traceRouteCtlOwnerIndex, is of type SnmpAdminString, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 2575 [11], VACM) and allows a management application to identify its entries. The second index, traceRouteCtlTestName (also an SnmpAdminString), enables the same management application to have multiple requests outstanding.

Traceroute has a much longer theoretical maximum time for completion than ping. Basically 42 hours and 30 minutes (the product of traceRouteCtlTimeOut, traceRouteCtlProbesPerHop, and traceRouteCtlMaxTtl) plus some network transit time! Use of the defaults defined within an traceRouteCtlEntry yields a maximum of 4 minutes and 30 seconds for a default traceroute operation. Clearly 42 plus hours is too long to wait for a traceroute operation to complete.

The maximum TTL value in effect for traceroute determines how long the traceroute function will keep increasing the TTL value in the probe it transmits hoping to reach the target host. The function ends whenever the maximum TTL is exceeded or the target host is reached. The object traceRouteCtlMaxFailures was created in order to impose a throttle for how long traceroute continues to increase the TTL field in a probe without receiving any kind of response (timeouts). It is RECOMMENDED that agent implementations impose a time limit for how long it allows a traceroute operation to take relative to how the function is implemented. For example, an implementation that can't process multiple traceroute operations at the same time SHOULD impose a shorter maximum allowed time period.

A management application can delete an active remote traceroute request by setting the corresponding traceRouteCtlRowStatus object to destroy(6).

The contents of the traceRouteCtlTable is preserved across reIPLs (Initial Program Loads) of its agent according to the values of each of the traceRouteCtlStorageType objects.

<u>**3.2.3</u>** traceRouteResultsTable</u>

DISMAN Working Group Expires September 2000 [Page 8]

Internet Draft Ping, Traceroute and Lookup MIBs March 1, 2000

An entry in the traceRouteResultsTable is created upon determining the results of a specific traceroute operation. Entries in this table relate back to the traceRouteCtlEntry that caused the corresponding traceroute operation to occur. The objects traceRouteResultsCurHopCount and traceRouteResultsCurProbeCount can be examined to determine how far the current remote traceroute operation has reached.

3.2.4 traceRouteProbeHistoryTable

The results of past traceroute probes can be stored in this table on a per traceRouteCtlEntry basis. This table is initially indexed by traceRouteCtlOwnerIndex and traceRouteCtlTestName in order for the results of a probe to relate to the traceRouteCtlEntry that caused it. The number of entries stored in this table per traceRouteCtlEntry is determined by the value of traceRouteCtlMaxRows.

An implementation of this MIB will remove the oldest entry in the traceRouteProbeHistoryTable to allow the addition of an new entry once the number of rows in the traceRouteProbeHistoryTable reaches the value of traceRouteCtlMaxRows. An implementation MUST start assigning traceRouteProbeHistoryIndex values at 1 and wrap after exceeding the maximum possible value as defined by the limit of this object ('ffffffff'h).

<u>3.2.5</u> traceRouteHopsTable

The current traceroute path can be stored in this table on a per traceRouteCtlEntry basis. This table is initially indexed by traceRouteCtlOwnerIndex and traceRouteCtlTestName in order for a traceroute path to relate to the traceRouteCtlEntry that caused it. A third index, traceRouteHopsHopIndex, enables keeping one traceRouteHopsEntry per traceroute hop. Creation of traceRouteHopsTable entries is enabled by setting the corresponding traceRouteCtlCreateHopsEntries object to true(1).

3.3 Lookup MIB

The DISMAN-NSLOOKUP-MIB consists of the following components:

- o lookupMaxConcurrentRequests, and lookupPurgeTime
- o lookupCtlTable
- o lookupResultsTable

<u>3.3.1</u> lookupMaxConcurrentRequests and lookupPurgeTime

The object lookupMaxConcurrentRequests enables control of the maximum number of concurrent active requests that an agent implementation is structured to support. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

DISMAN Working Group Expires September 2000

[Page 9]

Internet Draft Ping, Traceroute and Lookup MIBs March

March 1, 2000

The object lookupPurgeTime provides a method for entries in the lookupCtlTable and lookupResultsTable to be automatically deleted after the corresponding operation completes.

3.3.2 lookupCtlTable

A remote lookup operation is initiated by performing an SNMP SET request on lookupCtlRowStatus. A single SNMP PDU can be used to create and start a remote lookup operation. Within the PDU, lookupCtlTargetAddress should be set to the entity to be resolved (lookupCtlTargetAddressType will default to ipv4(1)) and lookupCtlRowStatus to createAndGo(4). The object lookupCtlOperStatus can be examined to determine the state of an lookup operation. A management application can delete an active remote lookup request by setting the corresponding lookupCtlRowStatus object to destroy(6).

An lookupCtlEntry is initially indexed by lookupCtlOwnerIndex, which is of type SnmpAdminString, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (<u>RFC 2575</u> [11], VACM) and also allows for a management application to identify its entries. The lookupCtlOwnerIndex portion of the index is then followed by lookupCtlOperationName. The lookupCtlOperationName index enables the same lookupCtlOwnerIndex entity to have multiple outstanding requests.

The value of lookupCtlTargetAddressType determines which lookup function to perform. Specification of dns(16) as the value of this index implies that the gethostbyname function should be performed to determine the numeric addresses associated with a symbolic name via lookupResultsTable entries. Use of a value of either ipv4(1) or ipv6(2) implies that the gethostbyaddr function should be performed to determine the symbolic name(s) associated with a numeric address at a remote host.

3.3.3 lookupResultsTable

The lookupResultsTable is used to store the results of lookup operations. The lookupResultsTable is initially indexed by the same index elements that the lookupCtlTable contains (lookupCtlOwnerIndex and lookupCtlOperationName) but has a third index element, lookupResultsIndex (Unsigned32 textual convention), in order to associate multiple results with the same lookupCtlEntry.

Both the gethostbyname and gethostbyaddr functions typically return a pointer to a hostent structure after being called. The hostent structure is defined as:

DISMAN Working Group Expires September 2000

[Page 10]

```
March 1, 2000
```

```
struct hostent {
    char *h_name; /* official host name */
    char *h_aliases[]; /* list of other aliases */
    int h_addrtype; /* host address type */
    int h_length; /* length of host address */
    char **h_addr_list; /* list of address for host */
};
```

The hostent structure is listed here in order to address the fact that a remote host can be multi-homed and can have multiple symbolic (DNS) names. It is not intended to imply that implementations of the DISMAN-LOOKUP-MIB are limited to systems where the hostent structure is supported.

The gethostbyaddr function is called with a host address as its parameter and is used primarily to determine a symbolic name to associate with the host address. Entries in the lookupResultsTable MUST be made for each host name returned. The official host name MUST be assigned a lookupResultsIndex of 1.

The gethostbyname function is called with a symbolic host name and is used primarily to retrieve a host address. Normally, the first h_addr_list host address is considered to be the primary address and as such is associated with the symbolic name passed on the call.

Entries MUST be stored in the lookupResultsTable in the order that they are retrieved. Values assigned to lookupResultsIndex MUST start at 1 and increase in order.

An implementation SHOULD NOT retain SNMP-created entries in the lookupTable across reIPLs (Initial Program Loads) of its agent, since management applications need to see consistent behavior with respect to the persistence of the table entries that they create.

     MAX-ACCESS not-accessible
     STATUS
                 current
     DESCRIPTION
        "To facilitate the provisioning of access control by a
        security administrator using the View-Based Access
        Control Model (RFC 2575, VACM) for tables in which
        multiple users may need to independently create or
        modify entries, the initial index is used as an 'owner
        index'. Such an initial index has a syntax of
        SnmpAdminString, and can thus be trivially mapped to a
        securityName or groupName as defined in VACM, in
        accordance with a security policy.
        When used in conjunction with such a security policy all
        entries in the table belonging to a particular user (or
        group) will have the same value for this initial index.
        For a given user's entries in a particular table, the
        object identifiers for the information in these entries
        will have the same subidentifiers (except for the 'column'
        subidentifier) up to the end of the encoded owner index.
        To configure VACM to permit access to this portion of the
        table, one would create vacmViewTreeFamilyTable entries
        with the value of vacmViewTreeFamilySubtree including
        the owner index portion, and vacmViewTreeFamilyMask
        'wildcarding' the column subidentifier. More elaborate
        configurations are possible."

     DESCRIPTION
         "The purpose of this object is to optionally enable
        bypassing the route table. If enabled, the remote
        host will bypass the normal routing tables and send
        directly to a host on an attached network. If the
        host is not on a directly-attached network, an
        error is returned. This option can be used to perform
        the ping operation to a local host through an
        interface that has no route defined (e.g., after the
        interface was dropped by routed)."
     DEFVAL { false }

     STATUS
                 current
     DESCRIPTION
          "Specifies the value to store in the Differentiated
         Services (DS) Field in the IP packet used to
         encapsulate the ping probe. The DS Field is defined
         as the Type of Service (TOS) octet in a IPv4 header
         or as the Traffic Class octet in a IPv6 header.
```

The value of this object must be a decimal integer in the range from 0 to 255. This option can be used to determine what effect an explicit DS Field setting

DISMAN Working Group Expires September 2000 [Page 22]

```
Internet Draft
                   Ping, Traceroute and Lookup MIBs
                                                         March 1, 2000
         has on a ping response. Not all values are legal or
         meaningful. A value of 0 means that the function
      represented by this option is not supported. DS Field
      usage is often not supported by IP implementations and
      not all values are supported. Refer to RFC 2474 for
      guidance on usage of this field."
     REFERENCE
         "Refer to RFC 2474 for the definition of the
         Differentiated Services Field and to RFC 1812
         Section 5.3.2 for Type of Service (TOS)."
     DEFVAL { 0 }

     SYNTAX
                RowStatus
     MAX-ACCESS read-create
     STATUS
                current
     DESCRIPTION
          "This object allows entries to be created and deleted
         in the pingCtlTable. Deletion of an entry in this
         table results in all corresponding (same
         pingCtlOwnerIndex and pingCtlTestName index values)
         pingResultsTable and pingProbeHistoryTable entries
         being deleted.
         A value MUST be specified for pingCtlTargetAddress
         prior to a transition to active(1) state being
         accepted.
         Activation of a remote ping operation is controlled
         via pingCtlAdminStatus and not by changing
         this object's value to active(1).
         Transitions in and out of active(1) state are not
         allowed while an entry's pingResultsOperStatus is
         active(1) with the exception that deletion of
         an entry in this table by setting its RowStatus
         object to destroy(6) will stop an active
         ping operation.
         The operational state of a ping operation
         can be determined by examination of its
         pingResultsOperStatus object."
     REFERENCE
         "See definition of RowStatus in RFC 2579, 'Textual
         Conventions for SMIv2.'"

traceRouteCtlOwnerIndex OBJECT-TYPE
SYNTAX SnmpAdminString (SIZE(0..32))
MAX-ACCESS not-accessible
STATUS current

DISMAN Working Group Expires September 2000 [Page 36]

DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (<u>RFC 2575</u>, VACM) for tables in which multiple users may need to independently create or modify entries, the initial index is used as an 'owner index'. Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

     MAX-ACCESS read-create
     STATUS
                  current
     DESCRIPTION
          "Specifies the value to store in the Differentiated
          Services (DS) Field in the IP packet used to
          encapsulate the traceroute probe. The DS Field is
          defined as the Type of Service (TOS) octet in a IPv4
          header or as the Traffic Class octet in a IPv6 header.
          The value of this object must be a decimal integer
          in the range from 0 to 255. This option can be used
          to determine what effect an explicit DS Field setting
```

has on a traceroute response. Not all values are legal

or meaningful. DS Field usage is often not supported by IP implementations. A value of 0 means that the function represented by this option is not supported. Useful TOS octet values are probably '16' (low delay)

DISMAN Working Group Expires September 2000 [Page 39]

     STATUS
                current
     DESCRIPTION
          "Use the specified IP address (which must be given
         as an IP number, not a hostname) as the source
         address in outgoing probe packets. On hosts with
         more than one IP address, this option can be used
         to force the source address to be something other
         than the primary IP address of the interface the
         probe packet is sent on. If the IP address is not
         one of this machine's interface addresses, an error
         is returned and nothing is sent. A zero length
         octet string value for this object disables source
         address specification.
         The address type (InetAddressType) that relates to
         this object is specified by the corresponding value
         of traceRouteCtlSourceAddressType."

lookupCtlEntry is initially indexed by lookupCtlOwnerIndex, which is of type SnmpAdminString, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (<u>RFC 2575 [11]</u>, VACM)

DISMAN Working Group Expires September 2000 [Page 61]

```
Internet Draft
                   Ping, Traceroute and Lookup MIBs
                                                           March 1, 2000
         and also allows an management application to identify
         its entries. The second index element,
         lookupCtlOperationName, enables the same
         lookupCtlOwnerIndex entity to have multiple outstanding
         requests.
         The value of lookupCtlTargetAddressType determines which
         lookup function to perform. Specification of dns(16)
         as the value of this index implies that the gethostbyname
         function should be performed to determine the numeric
         addresses associated with a symbolic name via
         lookupResultsTable entries. Use of a value of either
         ipv4(1) or ipv6(2) implies that the gethostbyaddr function
         should be performed to determine the symbolic name(s)
         associated with a numeric address at a remote host."

                 current
     STATUS
     DESCRIPTION
         "To facilitate the provisioning of access control by a
         security administrator using the View-Based Access
        Control Model (RFC 2575, VACM) for tables in which
        multiple users may need to independently create or
        modify entries, the initial index is used as an 'owner
        index'. Such an initial index has a syntax of
        SnmpAdminString, and can thus be trivially mapped to a
        securityName or groupName as defined in VACM, in
        accordance with a security policy.
        When used in conjunction with such a security policy all
```

entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries

DISMAN Working Group Expires September 2000 [Page 62]

```
Internet Draft
                   Ping, Traceroute and Lookup MIBs March 1, 2000
        will have the same subidentifiers (except for the
         'column' subidentifier) up to the end of the encoded
        owner index. To configure VACM to permit access to this
        portion of the table, one would create
        vacmViewTreeFamilyTable entries with the value of
        vacmViewTreeFamilySubtree including the owner index
        portion, and vacmViewTreeFamilyMask 'wildcarding' the
        column subidentifier. More elaborate configurations
        are possible."

         operation. All implementations MUST return a value
         of 0 for this object when the remote lookup
         operation succeeds. A non-zero value for this
         objects indicates failure. It is recommended that
         implementations that support errno use it as the
         value of this object to aid a management
         application in determining the cause of failure."
      ::= { lookupCtlEntry 7 }
```

lookupCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus MAX-ACCESS read-create STATUS current DESCRIPTION

DISMAN Working Group Expires September 2000

[Page 64]

"This object allows entries to be created and deleted in the lookupCtlTable.

A remote lookup operation is started when an entry in this table is created via an SNMP SET request and the entry is activated. This occurs by setting the value of this object to CreateAndGo(4) during row creation or by setting this object to active(1) after the row is created.

A value MUST be specified for lookupCtlTargetAddress prior to a transition to active(1) state being accepted.

A remote lookup operation starts when its entry first becomes active(1). Transitions in and out of active(1) state have no effect on the operational behavior of a remote lookup operation, with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active remote lookup operation.

The operational state of a remote lookup operation
 can be determined by examination of its
 lookupCtlOperStatus object."
REFERENCE
 "See definition of RowStatus in RFC 2579,
 'Textual Conventions for SMIv2.'"
::= { lookupCtlEntry 8 }

-- Lookup Results Table

lookupResultsTable OBJECT-TYPE
SYNTAX SEQUENCE OF LookupResultsEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION

"Defines the Lookup Results Table for providing the capability of determining the results of a operation at a remote host.

One or more entries are added to the lookupResultsTable when a lookup operation, as reflected by an lookupCtlEntry, completes successfully. All entries related to a successful lookup operation MUST be added to the lookupResultsTable at the same time that the associating lookupCtlOperStatus object is transitioned to completed(2).

DISMAN Working Group Expires September 2000 [Page 65]

```
Internet Draft
                    Ping, Traceroute and Lookup MIBs
                                                           March 1, 2000
         The number of entries added depends on the
         results determined for a particular lookup
         operation. All entries associated with an
         lookupCtlEntry are removed when the
         lookupCtlEntry is deleted.
         A remote host can be multi-homed and have more
         than one IP address associated with it
         (gethostbyname results) and/or it can have more
         than one symbolic name (gethostbyaddr results).
         The gethostbyaddr function is called with a
         host address as its parameter and is used
         primarily to determine a symbolic name to
         associate with the host address. Entries in
         the lookupResultsTable MUST be made for each
         host name returned. The official host name MUST
         be assigned a lookupResultsIndex of 1.
         The gethostbyname function is called with a
         symbolic host name and is used primarily to
         retrieve a host address. If possible the
         primary host address SHOULD be assigned a
         lookupResultsIndex of 1."

5.0 Security Considerations

Certain management information in the MIBs defined by this document may be considered sensitive in some network environments. Therefore, authentication of received SNMP requests and controlled access to management information SHOULD be employed in such environments. The method for this authentication is a function of the SNMP Administrative Framework, and has not been expanded by this MIB.

To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (VACM) defined in <u>RFC 2575</u> [11] for tables in which multiple users may need to independently create or modify entries, the initial index is used as an "owner index". Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

All entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the "column" subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask "wildcarding" the column subidentifier. More elaborate configurations are possible. The VACM access control mechanism described above provides control

In general both the ping and traceroute functions when used excessively are considered a form of system attack. In the case of ping sending a system requests too often can negatively effect its performance or attempting to connect to what is supposed to be an unused port can be very unpredictable. Excessive use of the traceroute capability can like ping negatively affect system performance. In insecure environments it is RECOMMENDED that the MIBs defined within this memo not be supported.

6.0 Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in BCP-11. Copies of claims of rights made available for publication and any assurances of

licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF Secretariat.
