Definitions of Managed Objects for the Delegation of Management Scripts

[<draft-ietf-disman-script-mib-08.txt>](#)

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC 2026](#). Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/ietf/1id-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at
<http://www.ietf.org/shadow.html>

Distribution of this document is unlimited. Please send comments to the Distributed Management Working Group, <disman@nexen.com>.

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes a set of managed objects that allow the delegation of management scripts to distributed managers.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [21].

2. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in [RFC 2271](#) [1].
- o Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIV1 and described in [RFC 1155](#) [2], [RFC 1212](#) [3] and [RFC 1215](#) [4]. The second version, called SMIV2, is described in [RFC 1902](#) [5], [RFC 1903](#) [6] and [RFC 1904](#) [7].
- o Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in [RFC 1157](#) [8]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in [RFC 1901](#) [9] and [RFC 1906](#) [10]. The third version of the message protocol is called SNMPv3 and described in [RFC 1906](#) [10], [RFC 2272](#) [11] and [RFC 2274](#) [12].
- o Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in [RFC 1157](#) [8]. A second set of protocol operations and associated PDU formats is described in [RFC 1905](#) [13].
- o A set of fundamental applications described in [RFC 2273](#) [14] and the view-based access control mechanism described in [RFC 2275](#) [15].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIV2. A MIB conforming to the SMIV1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIV2 will be converted into textual descriptions in SMIV1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

3. Overview

The Script MIB module defined in this memo can be used to delegate management functions to distributed managers. Management functions are defined as management scripts written in a management scripting language. This MIB makes no assumptions about the language itself and even allows distribution of compiled native code, if an implementation is able to execute native code under the control of this MIB.

The Script MIB defines a standard interface for the delegation of management functions based on the Internet management framework. In particular, it provides the following capabilities:

1. Capabilities to transfer management scripts to a distributed manager.
2. Capabilities for initiating, suspending, resuming and terminating management scripts.
3. Capabilities to transfer arguments for management scripts.
4. Capabilities to monitor and control running management scripts.
5. Capabilities to transfer the results produced by running management scripts.

This memo does not address any additional topics like the generation of notifications or how to address remote agents from a Script MIB implementation.

3.1. Terms

This section defines the terms used throughout this memo.

- o A 'distributed manager' is a processing entity which is capable of performing network management functions. For the scope of this memo, a distributed manager is assumed to implement the Script MIB.
- o A 'higher-level manager', or just 'manager', is a processing entity or human who initiates and controls the operations performed by one or more distributed managers.
- o A 'management script' is a set of instructions written in an executable language which implements a management function.
- o A 'management scripting language' is a language used to write management scripts. Note, the term scripting language does not imply that the language must have the characteristics of scripting languages (e.g. string orientation, interpretation, weak typing). The MIB defined in this memo also allows to control management scripts written in arbitrary compiled system programming languages.
- o A 'distributed manager' can be decomposed into an 'SNMP entity' which implements the Script MIB defined in this memo and the 'runtime system' that executes scripts. The Script MIB sees the runtime system as the managed resource which is controlled by the MIB.

The runtime system can act as an SNMP application, according to the SNMP architecture defined in [RFC 2271](#) [1]. For example, a runtime system which sends SNMP requests to other SNMP entities will act as a command generator application. The SNMP applications in the runtime system may use the same SNMP engine which also serves the command responder application used to implement the Script MIB, but they are not required to do so.

- o A 'launch button' is the conceptual button used to start the execution of a management script. It assigns control parameters to a management script. In particular, it defines the ownership of the scripts started from a launch button. The ownership can be used by the language runtime system to enforce security profiles on a running management script.

4. Requirements and Design Issues

This section discusses some general requirements that have influenced the design of the Script MIB.

- o The Script MIB must not make any assumptions about specific languages or runtime systems.
- o The Script MIB must provide mechanisms that help to avoid new management problems (e.g. script version problems).
- o The Script MIB must provide SNMP interfaces to all functions required to delegate management scripts. However, other protocols might be used in addition if they provide a significant improvement in terms of convenience for implementation or performance.
- o The Script MIB must be organized so that access can be controlled effectively by using view-based access control [[15](#)].

The following sections discuss some design issues in more detail.

4.1. Script Languages

The Script MIB defined in this memo makes no assumption about the script language. This MIB can therefore be used in combination with different languages (such as Tcl or Java) and/or different versions of the same language. No assumptions are made about the format in which management scripts are transferred.

The Script MIB provides access to information about the language versions supported by a Script MIB implementation so that a manager can learn about the capabilities provided by an implementation. Languages and language versions are identified as follows:

1. The language is identified by an object identifier. Object identifier for well-known languages will be registered by the Internet Assigned Numbers Authority (IANA). Enterprise specific languages can also be registered in the enterprise specific OID subtree.
2. A particular version of a language is identified by a language version number. The combination of a language object identifier and a language version is in most cases sufficient to decide whether a script can be executed or not.
3. Different implementations of the same language version might have differences due to ambiguities in the language definition or additional language features provided by an implementor. An additional object identifier value is provided which identifies the organization which provides the implementation of a

language. This might be used by scripts that require a particular implementation of a language.

4. Finally, there might be different versions of a language implementation. A version number for the language implementation is provided so that the manager can also distinguish between different implementations from the same organization of a particular language version.

The version numbers can either be used by a manager to select the language version required to execute a particular script or to select a script that fits the language versions supported by a particular Script MIB implementation.

An additional table lists language extensions that provide features not provided by the core language. Language extensions are usually required to turn a general purpose language into a management language. In many cases, language extensions will come in the form of libraries that provide capabilities like sending SNMP requests to remote SNMP agents or accessing the local MIB instrumentation. Every extension is associated with a language and carries its own version numbers.

4.2. Script Transfer

There are two different ways to transfer management scripts to a distributed manager. The first approach requires that the manager pushes the script to the distributed manager. This is therefore called the 'push model'. The second approach is the 'pull model' where the manager tells the distributed manager the location of the script and the distributed manager retrieves the script itself.

The MIB defined in this memo supports both models. The 'push model' is realized by a table which allows a manager to write scripts by sending a sequence of SNMP set requests. The script can be split into several fragments in order to deal with SNMP message size limitations.

The 'pull model' is realized by the use of Uniform Resource Locators (URLs) [17] that point to the script source. The manager writes the URL which points to the script source to the distributed manager by sending an SNMP set request. The distributed manager is then responsible for retrieving the document using the protocol specified in the URL. This allows the use of protocols like FTP [18] or HTTP [19] to transfer large management scripts efficiently.

The Script MIB also allows management scripts that are hard-wired into the Script MIB implementation. Built-in scripts can either be implemented in a language runtime system, or they can be built natively into the Script MIB implementation. The implementation of the 'push model' or the 'pull model' is not required.

Scripts can be stored in non-volatile storage. This allows a distributed manager to restart scripts if it is restarted (off-line restart). A manager is not required to push scripts back into the distributed manager after a restart if the script is backed up in non-volatile storage.

Every script is identified by an administratively assigned name. This name may be used to derive the name which is used to access the script in non-volatile storage. This mapping is implementation specific. However, the mapping must ensure that the Script MIB implementation can handle scripts with the same administrative name owned by different managers. One way to achieve this is to use the script owner in addition to the script name in order to derive the internal name used to refer to a particular script in non-volatile storage.

4.3. Script Execution

The Script MIB permits execution of several instances of the same or different management scripts. Script arguments are passed as OCTET STRING values. Scripts return a single result value which is also an OCTET STRING value. The semantic interpretation of result values is left to the invoking manager or other management scripts. A script invoker must understand the format and semantics of both the arguments and the results of the scripts that it invokes.

Scripts can also export complex results through a MIB interface. This allows a management application to access and use script results in the same manner as it processes any other MIB data. However, the Script MIB does not provide any special support for the implementation of MIBs through scripts.

Runtime errors terminate active scripts. An exit code and a human readable error message is left in the MIB. A notification containing the exit code, the error message and a timestamp is generated when a script terminates with an error exit code.

Script arguments and results do not have any size limitations other than the limits imposed by the SMI and the SNMP protocol. However, implementations of this MIB might have further restrictions. A script

designer might therefore choose to return the results via other mechanisms if the script results can be very large. One possibility is to return a URL as a script result which points to the file containing the script output.

Executing scripts have a status object attached which allows script execution to be suspended, resumed, or aborted. The precise semantics of the suspend and resume operations are language and runtime system dependent. Some runtime systems may choose to not implement the suspend/resume operations.

A history of finished scripts is kept in the MIB. A script invoker can collect results at a later point in time (offline operation). Control objects can be used to control how entries in the history are aged out if the table fills up.

5. The Structure of the MIB

This section presents the structure of the MIB. The objects are arranged into the following groups:

- o language group (smLanguageGroup)
- o script group (smScriptGroup)
- o script code group (smCodeGroup)
- o script launch group (smLaunchGroup)
- o running script group (smRunGroup)

5.1. The smLanguageGroup

The smLanguageGroup is used to provide information about the languages and the language extensions supported by a Script MIB implementation. This group includes two tables. The smLangTable lists all languages supported by a Script MIB implementation and the smExtnTable lists the extensions that are available for a given language.

5.2. The smScriptGroup

The smScriptGroup consists of a single table, called the smScriptTable. The smScriptTable lists all scripts known to a Script

MIB implementation. The smScriptTable contains objects that allow the following operations:

- o download scripts from a URL (pull model)
- o read scripts from local non-volatile storage
- o store scripts in local non-volatile storage
- o delete scripts from local non-volatile storage
- o list permanent scripts (that can not be changed or removed)
- o read and modify the script status (enabled, disabled, editing)

A status object called smScriptOperStatus allows a manager to obtain the current status of a script. It is also used to provide an error indication if an attempt to invoke one of the operations listed above fails. The status change of a script can be requested by modifying the associated smScriptAdminStatus object.

The source of a script is defined by the smScriptSource object. This object may contain a URL pointing to a remote location which provides access to the management script. The script source is read from the smCodeTable (described below) or from non-volatile storage if the smScriptSource object contains an empty URL. The smScriptStorageType object is used to distinguish between scripts read from non-volatile storage and scripts read from the smCodeTable.

Scripts are automatically loaded once the smScriptAdminStatus object is set to 'enabled'. Loading a script includes retrieving the script (probably from a remote location), compiling the script for languages that require a compilation step, and making the code available to the runtime system. The smScriptOperStatus object is used to indicate the status of the loading process. This object will start in the state 'retrieving', switch to the state 'compiling' and finally reach the state 'enabled'. Errors during the retrieval or compilation phase will result in an error state such as 'compilationFailed'.

5.3. The smCodeGroup

The smCodeGroup consists of a single table, called the smCodeTable, which provides the ability to transfer and modify scripts via SNMP set requests. In particular, the smCodeTable allows the following operations:

- o download scripts via SNMP (push model)
- o modify scripts via SNMP (editing)

The smCodeTable lists the code of a script. A script can be fragmented over multiple rows of the smCodeTable in order to handle SNMP message size limitations. Modifications of the smCodeTable are only possible if the associated smScriptOperStatus object has the value 'editing'. The Script MIB implementation reloads the modified script code once the smScriptOperStatus changes to 'enabled' again.

The implementation of the smCodeGroup is optional.

5.4. The smLaunchGroup

The smLaunchGroup contains a single table, the smLaunchTable. An entry in the smLaunchTable represents a launch button which can be used to start a script. The smLaunchTable allows the following operations:

- o associate a script with an owner used during script execution
- o provide arguments and parameters for script invocation
- o invoke scripts with a single set operation

The smLaunchTable describes scripts and their parameters that are ready to be launched. An entry in the smLaunchTable attaches an argument to a script and control values which, for example, define the maximum number of times that a script invoked from a particular row in the smLaunchTable may be running concurrently.

An entry in the smLaunchTable also defines the owner which will be used to associate permissions with the script execution.

5.5. The smRunGroup

The smRunGroup contains a single table, called the smRunTable, which lists all scripts that are currently running or have terminated recently. The smRunTable contains objects that allow the following operations:

- o retrieve status information from running scripts

- o control running scripts (suspend, resume, abort)
- o retrieve results from recently terminated scripts
- o control the remaining maximum lifetime of a running script
- o control how long script results are accessible

Every row in the smRunTable contains the argument passed during script invocation, the result produced by the script and the script exit code. The smRunTable also provides information about the current run state as well as start and end time-stamps. There are three writable objects in the smRunTable. The smRunLifeTime object defines the maximum time a running script may run before it is terminated by the Script MIB implementation. The smRunExpireTime object defines the time that a completed script can stay in the smRunTable before it is aged out. The smRunControl object allows running scripts to be suspended, resumed, or aborted.

STATUS current

DESCRIPTION

"This object either contains a reference to the script source or an empty string. A reference must be given in the form of a Uniform Resource Locator (URL) as defined in [RFC 2396](#). The allowed character sets and the encoding rules defined in [RFC 2396 section 2](#) apply.

When the smScriptAdminStatus object is set to 'enabled', the Script MIB implementation will 'pull' the script source from the URL contained in this object if the URL is not empty.

An empty URL indicates that the script source is loaded from local storage. The script is read from the smCodeTable if the value of smScriptStorageType is volatile. Otherwise, the script is read from non-volatile storage.

Note: This document does not mandate implementation of any specific URL scheme. A attempt to load a script from a nonsupported URL scheme will cause the smScriptOperStatus to report an 'unknownProtocol' error.

Set requests to change this object are invalid if the value of smScriptOperStatus is 'enabled', 'editing', 'retrieving' or 'compiling' and will result in an inconsistentValue error."

DESCRIPTION

"The actual status of the script in the runtime system. The value of this object is only meaningful when the value of the smScriptRowStatus object is 'active'.

The smScriptOperStatus object may have the following values:

- ``enabled'` indicates that the script is available and can be started by a launch table entry.
- ``disabled'` indicates that the script can not be used.
- ``editing'` indicates that the script can be modified in the `smCodeTable`.
- ``retrieving'` indicates that the script is currently being loaded from non-volatile storage or a remote system.
- ``compiling'` indicates that the script is currently being compiled by the runtime system.
- ``noSuchScript'` indicates that the script does not exist at the `smScriptSource`.
- ``accessDenied'` indicates that the script can not be loaded from the `smScriptSource` due to a lack of permissions.
- ``wrongLanguage'` indicates that the script can not be loaded from the `smScriptSource` because of a language mismatch.
- ``wrongVersion'` indicates that the script can not be loaded from the `smScriptSource` because of a language version mismatch.
- ``compilationFailed'` indicates that the compilation failed.
- ``noResourcesLeft'` indicates that the runtime system does not have enough resources to load the script.
- ``unknownProtocol'` indicates that the script could not be loaded from the `smScriptSource` because the requested protocol is not supported.
- ``protocolFailure'` indicates that the script could not be loaded from the `smScriptSource` because of a protocol failure.
- ``genericError'` indicates that the script could not be loaded due to an error condition not listed above.

The ``retrieving'` and ``compiling'` states are transient states which will either lead to one of the error states or the ``enabled'` state. The ``disabled'` and ``editing'` states are administrative states which are only reached by explicit

management operations.

All launch table entries that refer to this script table entry shall have an smLaunchOperStatus value of `disabled' when the value of this object is not `enabled'."

```

::= { smScriptEntry 7 }
```

smScriptStorageType OBJECT-TYPE

```
SYNTAX      StorageType  
MAX-ACCESS  read-create  
STATUS      current  
DESCRIPTION
```

"This object defines whether this row and the script controlled by this row are kept in volatile storage and lost upon reboot or if this row is backed up by non-volatile or permanent storage.

The script controlled by this row is written into local non-volatile storage if the following condition becomes true:

- (a) the URL contained in the smScriptSource object is empty
and
- (b) the smScriptStorageType is `nonVolatile'
and
- (c) the smScriptOperStatus is `enabled'

Setting this object to `volatile' removes a script from non-volatile storage if the script controlled by this row has been in non-volatile storage before. Attempts to set this object to permanent will always fail with an inconsistentValue error.

The value of smScriptStorageType is only meaningful if the value of the corresponding RowStatus object is `active'.

If smScriptStorageType has the value permanent(4), then all objects whose MAX-ACCESS value is read-create must be writable, with the exception of the smScriptStorageType and smScriptRowStatus objects, which shall be read-only."

```
DEFVAL { volatile }  
::= { smScriptEntry 8 }
```

smScriptRowStatus OBJECT-TYPE

```
SYNTAX      RowStatus  
MAX-ACCESS  read-create
```

STATUS current

DESCRIPTION

"A control that allows entries to be added and removed from this table.

Changing the smScriptRowStatus from 'active' to 'notInService' will remove the associated script from the runtime system. The value of smScriptOperStatus will be reset to 'disabled'.

Deleting conceptual rows from this table includes the deletion of all resources associated with this row. This implies that a script stored in non-volatile storage is removed from non-volatile storage.

An entry may not exist in the 'active' state unless all required objects in the entry have appropriate values. Rows that are not complete or not in service are not known by the script runtime system.

Attempts to 'destroy' a row or to set a row 'notInService' while the script is executing will result in an inconsistentValue error.

Attempts to 'destroy' a row or to set a row 'notInService' where the value of the smScriptStorageType object is 'permanent' or 'readOnly' will result in an inconsistentValue error."

The value of this object is used to initialize the smRunExpireTime object when a script is launched. Changing the value of an smLaunchExpireTime instance does not affect scripts previously launched from this entry."

DEFVAL { 360000 }
::= { smLaunchEntry 9 }

smLaunchStart OBJECT-TYPE

SYNTAX Integer32 (0..2147483647)
MAX-ACCESS read-create
STATUS current
DESCRIPTION

"This object is used to start the execution of scripts. When retrieved, the value will be the value of smRunIndex for the last script that started execution by manipulating this object. The value will be zero if no script started execution yet.

A script is started by setting this object to an unused smRunIndex value. A new row in the smRunTable will be created which is indexed by the value supplied by the set-request in addition to the value of smLaunchOwner and smLaunchName. An unused value can be obtained by reading the smLaunchRunIndexNext object.

Setting this object to the special value 0 will start the script with a self-generated smRunIndex value. The consequence is that the script invoker has no reliable way to determine the smRunIndex value for this script invocation and that the invoker has therefore no way to obtain the results from this script invocation. The

special value 0 is however useful for scheduled script invocations.

If this object is set, the following checks must be performed:

- 1) The value of the smLaunchOperStatus object in this entry of the smLaunchTable must be 'enabled'.
- 2) The values of smLaunchScriptOwner and smLaunchScriptName of this row must identify an existing entry in the smScriptTable.
- 3) The value of smScriptOperStatus of this entry must be 'enabled'.
- 4) The principal performing the set operation must have read access to the script. This must be checked by calling the isAccessAllowed abstract service interface defined in [RFC 2271](#) on the row in the smScriptTable identified by smLaunchScriptOwner and smLaunchScriptName. The isAccessAllowed abstract service interface must be called on all columnar objects in the smScriptTable with a MAX-ACCESS value different than 'not-accessible'. The test fails as soon as a call indicates that access is not allowed.
- 5) If the value provided by the set operation is not 0, a check must be made that the value is currently not in use. Otherwise, if the value provided by the set operation is 0, a suitable unused value must be generated.
- 6) The number of currently executing scripts invoked from this smLaunchTable entry must be less than smLaunchMaxRunning.

Attempts to start a script will fail with an inconsistentValue error if one of the checks described above fails.

Otherwise, if all checks have been passed, a new entry in the smRunTable will be created indexed by smLaunchOwner, smLaunchName and the new value for smRunIndex. The value of smLaunchArgument will be copied into smRunArgument, the value of smLaunchLifeTime will be copied to smRunLifeTime, and the value of smLaunchExpireTime will be copied to smRunExpireTime.

The smRunStartTime will be set to the current time and the smRunState will be set to 'initializing' before the script execution is initiated in the appropriate runtime

system.

Note, the data type and the range of this object must be consistent with the smRunIndex object. Since this object might be written from the scheduling MIB, the data type Integer32 rather than Unsigned32 is used."

7. Usage Examples

This section presents some examples that explain how a manager can use the Script MIB defined in this memo. The purpose of these examples is to explain the steps that are normally used to delegate management scripts.

7.1. Pushing a script via SNMP

This example explains the steps performed by a manager to push a script into a distributed manager.

1. The manager first checks the smLanguageTable and the smExtensionTable in order to select the appropriate script or language.
2. The manager creates a row in the smScriptTable by issuing an SNMP set-request. The smScriptRowStatus object is set to 'createAndWait' and the smScriptSource object is set to an empty string. The smScriptLanguage object is set to the language in which the script was written. The smScriptStorageType object is set to 'volatile' to indicate that the script will be loaded via the smCodeTable. The smScriptOwner is set to a string which identifies the principal who owns the new row. The smScriptName defines the administratively assigned unique name for the script.
3. The manager sets the smScriptRowStatus object to 'active' and the smScriptAdminStatus object to 'editing'.
4. The manager pushes the script to the distributed manager by issuing a couple of SNMP set-requests to fill the smCodeTable.
5. Once the whole script has been transferred, the manager sends a set-request to set the smScriptAdminStatus object to 'enabled'. The Script MIB implementation now makes the script accessible to the runtime system. This might include the compilation of the script if the language requires a compilation step.
6. The manager polls the smScriptOperStatus object until the value is either 'enabled' or one of the error status codes. The script can only be used if the value of smScriptOperStatus is 'enabled'.
7. If the manager wants to store the script in local non-volatile storage, it should send a set-request which changes the

smScriptStorageType object to `nonVolatile'.

7.2. Pulling a script from a URL

This example explains the steps performed by a manager to cause a distributed manager to pull a script from a URL.

1. The manager first checks the smLanguageTable and the smExtensionTable in order to select the appropriate script or language.
2. The manager creates a row in the smScriptTable by issuing an SNMP set-request. The smScriptRowStatus object is set to `createAndWait' and the smScriptSource object is set to the URL which points to the script source. The smScriptLanguage object is set to the language in which the script was written. The smScriptOwner is set to a string which identifies the principal who owns the new row. The smScriptName defines the administratively assigned unique name for the script.
3. The manager sets the smScriptRowStatus object to `active'.
4. The manager sends a set-request to set the smScriptAdminStatus object to `enabled'. The Script MIB implementation now makes the script accessible to the runtime system. This causes a retrieval operation to pull the script from the URL stored in smScriptSource. This retrieval operation might be followed by a compile operation if the language requires a compilation step.
5. The manager polls the smScriptOperStatus object until the value is either `enabled' or one of the error status codes. The script can only be used if the value of smScriptOperStatus is `enabled'.
6. If the manager wants to store the script in local non-volatile storage, it should send a set-request which changes the smScriptStorageType object to `nonVolatile'.

7.3. Modifying an existing script

This section explains how a manager can modify a script by sending SNMP set-requests.

1. First, the script is de-activated by setting the smScriptAdminStatus to `disabled'.

2. The manager polls the smScriptOperStatus object until the value is 'disabled'.
3. The manager sets smScriptSource to an empty string and smScriptAdminStatus to 'editing'. This makes the script source available in the smCodeTable.
4. The manager polls the smScriptOperStatus object until the value is 'editing'.
5. The manager sends SNMP set-requests to modify the script in the smCodeTable.
6. The manager sends a set-request to set the smScriptAdminStatus object to 'enabled'. The Script MIB implementation now makes the script accessible to the runtime system. This might include the compilation of the script if the language requires a compilation step.
7. The manager polls the smScriptOperStatus object until the value is either 'enabled' or one of the error status codes. The script can only be used if the value of smScriptOperStatus is 'enabled'.

7.4. Removing an existing script

This section explains how a manager can remove a script from a distributed manager.

1. First, the manager sets the smScriptAdminStatus to 'disabled'. This will ensure that no new scripts can be started while running scripts finish their execution.
2. The manager polls the smScriptOperStatus object until the value is 'disabled'.
3. The manager sends an SNMP set-request to change the smScriptRowStatus object to 'destroy'. This will remove the row and all associated resources from the Script MIB implementation.

7.5. Creating a launch button

This section explains how a manager can create a launch button for starting a script.

1. The manager, who is identified by an `smLaunchOwner` value, first chooses a name for the new row in the `smLaunchTable`. The manager sends an SNMP set-request to set the `smLaunchRowStatus` object for this `smLaunchOwner` and `smLaunchName` to `'createAndWait'`.
2. The manager fills the new `smLaunchTable` row with all required parameters. The `smLaunchScriptOwner` and `smLaunchScriptName` values point to the script that should be started from this launch button.
3. The manager sends a set-request to change `smLaunchAdminStatus` to `'enabled'` once the new `smLaunchTable` row is complete.
4. The manager polls the `smLaunchOperStatus` object until the value is `'enabled'`.

7.6. Launching a script

This section explains the suggested way to launch a script from a given launch button.

1. The manager first retrieves the value of `smLaunchRunIndexNext` from the launch button selected to start the script.
2. The manager sends an SNMP set-request to set the `smLaunchStart` object to the value obtained in step 1. This will launch the script if all necessary pre-conditions are satisfied (see the definition of `smLaunchStart` for more details). The manager can also provide the `smLaunchArgument` in the same set-request that is used to start the script. Upon successful start, a new row will be created in the `smRunTable` indexed by `smLaunchOwner`, `smLaunchName` and the value written to `smLaunchStart`.

Note, the first step is not required. A manager can also try to guess an unused value for `smRunIndex` if he wants to start script in a single transaction. A manager can also use the special value 0 if he does not care about the results produced by the script.

7.7. Terminating a script

This section explains two ways to terminate a running script. The first approach is as follows:

1. The manager sets the `smRunControl` object of the running script or the `smLaunchControl` object of the launch button used to start

the running script to ``abort'`. Setting `smLaunchControl` will abort all running scripts started from the launch button while `smRunControl` will only abort the running script associated with the `smRunControl` instance.

The second way to terminate a script is to set the `smRunLifeTime` to zero which causes the runtime system to terminate the script with a ``lifeTimeExceeded'` exit code:

1. The manager changes the value of `smRunLifeTime` to 0. This causes the Script MIB implementation to abort the script because the remaining life time has expired.

Note, changing the `smRunLifeTime` value can also be used to increase the permitted lifetime of a running script. For example, a manager can choose to set `smRunLifeTime` to a small fixed time interval and increase the value periodically. This strategy has the nice effect that scripts terminate automatically if the manager loses contact with the Script MIB engine.

7.8. Removing a launch button

This section explains how a manager can remove a launch button from a distributed manager.

1. First, the manager sets the `smLaunchAdminStatus` to ``disabled'`. This will ensure that no new scripts can be started from this launch button while running script will finish their execution.
2. The manager polls the `smLaunchOperStatus` object until the value is ``disabled'`.
3. The manager sends an SNMP set-request to change the `smLaunchRowStatus` object to ``destroy'`. This will remove the row and all associated resources from the Script MIB implementation.

8. VACM Configuration Examples

This section shows how the view-based access control model defined in [RFC 2275](#) [15] can be configured to control access to the script MIB.

8.1. Sandbox for guests

The first example demonstrates how to configure VACM to give the members of the VACM group "guest" limited access to the script MIB. The MIB views defined below give the members of the "guest" group a sandbox where they can install and start their own scripts, but not access any other scripts maintained by the Script MIB implementation.

```
vacmAccessReadView."guest"."".usm.authNoPriv = "guestReadView"  
vacmAccessWriteView."guest"."".usm.authNoPriv = "guestWriteView"
```

The guestReadView grants read access to the smLangTable, the smExtsnTable and to all the table entries owned by "guest":

```
guestReadView:  
    smLangTable                (included)  
    smExtsnTable               (included)  
    smScriptObjects.*.*.*."guest" (included)  
    smRunObjects.*.*.*."guest"   (included)
```

The guestWriteView grants write access to all the table entries owned by "guest":

```
guestWriteView:  
    smScriptObjects.*.*.*."guest" (included)  
    smRunObjects.*.*.*."guest"   (included)
```

8.2. Sharing scripts

This example demonstrates how VACM can be used to share a repository of scripts between the members of the "senior" and the members of the "junior" VACM group:

```
vacmAccessReadView."junior"."".usm.authNoPriv = "juniorReadView"  
vacmAccessWriteView."junior"."".usm.authNoPriv = "juniorWriteView"
```

```
juniorReadView:
```

```
smLangTable                (included)
smExtsnTable               (included)
smScriptObjects.*.*.*"junior" (included)
smRunObjects.*.*.*"junior"   (included)
smScriptObjects.*.*.*"utils" (included)

juniorWriteView:
  smScriptObjects.*.*.*"junior" (included)
  smRunObjects.*.*.*"junior"   (included)
```

The definitions above allow the members of the "junior" VACM group to start the scripts owned by "utils" in addition to the script the members of the "junior" VACM group installed themselves. This is accomplished by giving the members of "junior" read access to scripts in "utils". This allows members of "junior" to create entries in the smLaunchTable which refer to scripts in "utils", and to launch those scripts using these entries in the smLaunchTable.

```
vacmAccessReadView."senior"."".usm.authNoPriv = "seniorReadView"
vacmAccessWriteView."senior"."".usm.authNoPriv = "seniorWriteView"
```

```
seniorReadView:
  smLangTable                (included)
  smExtsnTable               (included)
  smScriptObjects.*.*.*"senior" (included)
  smRunObjects.*.*.*"senior"   (included)
  smScriptObjects.*.*.*"utils" (included)

seniorWriteView:
  smScriptObjects.*.*.*"senior" (included)
  smRunObjects.*.*.*"senior"   (included)
  smScriptObjects.*.*.*"utils" (included)
```

The definitions for the members of the "senior" VACM group allow to start the scripts owned by "utils" in addition to the script the members of the "senior" VACM group installed themselves. The third write access rule in the seniorWriteView also grants the permission to install scripts owned by "utils". The members of the "senior" VACM group therefore have the permissions to install and modify scripts that can be called by the members of the "junior" VACM group.

8.3. Emergency scripts

This example demonstrates how VACM can be used to allow the members

of the "junior" VACM group to launch scripts that are executed with the permissions associated with the "emergency" owner. This works by adding the following rules to the juniorReadView and the juniorWriteView:

```
juniorReadView:
    smScriptObjects.*.*.*."emergency" (included)
    smRunObjects.*.*.*."emergency"    (included)

juniorWriteView
    smLaunchStart."emergency"          (included)
    smLaunchArgument."emergency"       (included)
```

The rules added to the juniorReadView grant read access to the scripts, the launch buttons and the results owned by "emergency". The rules added to the juniorWriteView grant write permissions to the smLaunchStart and smLaunchArgument variables owned by "emergency". Members of the "junior" VACM group can therefore start scripts that will execute under the owner "emergency".

```
seniorReadView:
    smScriptObjects.*.*.*."emergency" (included)
    smRunObjects.*.*.*."emergency"    (included)

seniorWriteView:
    smScriptObjects.*.*.*."emergency" (included)
    smRunObjects.*.*.*."emergency"    (included)
```

The rules added to the seniorReadView and the seniorWriteView will give the members of the "senior" VACM group the rights to install emergency scripts and to configure appropriate launch buttons.

9. IANA Considerations

The Internet Assigned Numbers Authority (IANA) is responsible for maintaining a MIB module which provides OID registrations for well-known languages. The IANA language registry is intended to reduce interoperability problems by providing a single list of well-known languages. However, it is of course still possible to register languages in private OID spaces. Registering languages in private spaces is especially attractive if a language is used for experimentation or if a language is only used in environments where the distribution of MIB modules with the language registration does not cause any maintenance problems.

Any additions or changes to the list of languages registered via IANA

require Designated Expert Review as defined in the IANA guidelines [20]. The Designated Expert will be selected by the IESG Area Director for the IETF Operations and Management Area.

10. Security Considerations

This MIB provides the ability to distribute applications written in an arbitrary language to remote systems in a network. The security features of the languages available in a particular implementation should be taken into consideration when deploying an implementation of this MIB.

To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (VACM) defined in RFC 2275 [15] for tables in which multiple users may need to independently create or modify entries, the initial index is used as an "owner index". Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

All entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the "column" subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask "wildcarding" the column subidentifier. More elaborate configurations are possible.

The VACM access control mechanism described above provides control over SNMP access to Script MIB objects. There are a number of other access control issues that are outside of the scope of this MIB. For example, access control on URLs, especially those that use the file scheme, must be realized by the underlying operating system. A mapping of the owner index value to a local operating system security user identity should be used by an implementation of this MIB to control access to operating system resources when resolving URLs or executing scripts.

11. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in [BCP-11](#). Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.

12. Acknowledgments

This document was produced by the IETF Distributed Management (DISMAN) working group.

16. IANA Language Registration MIB

This appendix defines the initial content of the IANA-LANGUAGE-MIB. This section should be removed from this document prior to its approval, at which time this MIB will be administered by IANA.

```
IANA-LANGUAGE-MIB DEFINITIONS ::= BEGIN
```

```
IMPORTS
```

```
    MODULE-IDENTITY, OBJECT-IDENTITY, experimental
    FROM SNMPv2-SMI;
```

```
ianaLanguages MODULE-IDENTITY
```

```
    LAST-UPDATED "9902221800Z"
```

```
    ORGANIZATION "IANA"
```

```
    CONTACT-INFO
```

```
        "Internet Assigned Numbers Authority (IANA)
```

```
        Postal: USC/Information Sciences Institute
                4676 Admiralty Way, Marina del Rey, CA 90292
```

```
        Tel:    +1 310 822 1511
```

```
        E-Mail: iana@isi.edu"
```

```
DESCRIPTION
```

```
"The MIB module registers object identifier values for
well-known programming and scripting languages. Every
language registration MUST describe the format used
when transferring scripts written in this language.
```

```
Any additions or changes to the contents of this MIB
module require Designated Expert Review as defined in
the Guidelines for Writing IANA Considerations Section
document. The Designated Expert will be selected by
the IESG Area Director of the OPS Area.
```

```
Note, this module does not have to register all possible
languages since languages are identified by object identifier
values. It is therefore possible to registered languages in
private OID trees.
```

```
The references given below are not normative with regard to
the language version. Other references might be better suited
to describe some newer versions of this language. The
references are only provided as `a pointer into the right
direction'."
```

```
-- XXX Replace with real registration number from IANA. Note, the
```

```
-- XXX IMPORTS must be updated when the real number is assigned.
::= { experimental 9876 }
```

ianaLangJavaByteCode OBJECT-IDENTITY

STATUS current

DESCRIPTION

"Java byte code to be processed by a Java virtual machine.
A script written in Java byte code is transferred by using
the Java archive file format (JAR)."

REFERENCE

"The Java Virtual Machine Specification.
ISBN 0-201-63452-X"

::= { ianaLanguages 1 }

ianaLangTcl OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The Tool Command Language (Tcl). A script written in the
Tcl language is transferred in Tcl source code format."

REFERENCE

"Tcl and the Tk Toolkit.
ISBN 0-201-63337-X"

::= { ianaLanguages 2 }

ianaLangPerl OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The Perl language. A script written in the Perl language
is transferred in Perl source code format."

REFERENCE

"Programming Perl.
ISBN 1-56592-149-6"

::= { ianaLanguages 3 }

ianaLangScheme OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The Scheme language. A script written in the Scheme
language is transferred in Scheme source code format."

REFERENCE

"The Revised⁴ Report on the Algorithmic Language Scheme.
MIT Press"

::= { ianaLanguages 4 }

ianaLangSRSL OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The SNMP Script Language defined by SNMP Research. A script written in the SNMP Script Language is transferred in the SNMP Script Language source code format."
::= { ianaLanguages 5 }

ianaLangPSL OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The Patrol Script Language defined by BMC Software. A script written in the Patrol Script Language is transferred in the Patrol Script Language source code format."

REFERENCE

"PATROL Script Language Reference Manual, Version 3.0, November 30, 1995. BMC Software, Inc. 2101 City West Blvd., Houston, Texas 77042."

::= { ianaLanguages 6 }

ianaLangSMSL OBJECT-IDENTITY

STATUS current

DESCRIPTION

"The Systems Management Scripting Language. A script written in the SMSL language is transferred in the SMSL source code format."

REFERENCE

"ISO/ITU Command Sequencer.
ISO 10164-21 or ITU X.753"

::= { ianaLanguages 7 }
