# Message Digest for DNS Zones draft-ietf-dnsop-dns-zone-digest-09

### Abstract

This document describes a protocol and new DNS Resource Record that can be used to provide a cryptographic message digest over DNS zone data. The ZONEMD Resource Record conveys the digest data in the zone itself. When a zone publisher includes an ZONEMD record, recipients can verify the zone contents for accuracy and completeness. This provides assurance that received zone data matches published data, regardless of how the zone data has been transmitted and received.

ZONEMD is not designed to replace DNSSEC. Whereas DNSSEC protects individual RRSets (DNS data with fine granularity), ZONEMD protects a zone's data as a whole, whether consumed by authoritative name servers, recursive name servers, or any other applications.

As specified at this time, ZONEMD is not designed for use in large, dynamic zones due to the time and resources required for digest calculation. The ZONEMD record described in this document is designed so that new digest schemes may be developed in the future to support large, dynamic zones.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of <u>BCP 78</u> and <u>BCP 79</u>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <u>https://datatracker.ietf.org/drafts/current/</u>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any

## **<u>1</u>**. Introduction

In the DNS, a zone is the collection of authoritative resource records (RRs) sharing a common origin ([RFC8499]). Zones are often stored as files on disk in the so-called master file format [RFC1034]. Zones are generally distributed among name servers using the AXFR [RFC5936], and IXFR [RFC1995] protocols. Zone files can also be distributed outside of the DNS, with such protocols as FTP, HTTP, and rsync, and even via email. Currently there is no standard way to verify the authenticity of a stand-alone zone.

This document introduces a new RR type that serves as a cryptographic message digest of the data in a zone. It allows a receiver of the zone to verify the zone's authenticity, especially when used in combination with DNSSEC. This technique makes the digest a part of the zone itself, allowing verification the zone as a whole, no matter

[Page 3]

how it is transmitted. Furthermore, the digest is based on the wire format of zone data. Thus, it is independent of presentation format, such as changes in whitespace, capitalization, and comments.

DNSSEC provides three strong security guarantees relevant to this protocol:

- 1. whether or not to expect DNSSEC records in the zone,
- 2. whether or not to expect a ZONEMD record in a signed zone, and
- whether or not the ZONEMD record has been altered since it was signed.

This specification is OPTIONAL to implement by both publishers and consumers of zone data.

## **<u>1.1</u>**. Motivation

The motivation for this protocol enhancement is the desire for the ability to verify the authenticity of a stand-alone zone, regardless of how it is transmitted. A consumer of zone data should be able to verify that the data is as-published by the zone operator.

One approach to preventing data tampering and corruption is to secure the distribution channel. The DNS has a number of features that can already be used for channel security. Perhaps the most widely used is DNS transaction signatures (TSIG [<u>RFC2845</u>]). TSIG uses shared secret keys and a message digest to protect individual query and response messages. It is generally used to authenticate and validate UPDATE [<u>RFC2136</u>], AXFR [<u>RFC5936</u>], and IXFR [<u>RFC1995</u>] messages.

DNS Request and Transaction Signatures (SIG(0) [RFC2931]) is another protocol extension designed to authenticate individual DNS transactions. Whereas SIG records were originally designed to cover specific RR types, SIG(0) is used to sign an entire DNS message. Unlike TSIG, SIG(0) uses public key cryptography rather than shared secrets.

The Transport Layer Security protocol suite is also designed to provide channel security. One can easily imagine the distribution of zones over HTTPS-enabled web servers, as well as DNS-over-HTTPS [<u>RFC8484</u>], and perhaps even a future version of DNS-over-TLS ([<u>RFC7858</u>]).

Unfortunately, the protections provided by these channel security techniques are (in practice) ephemeral and are not retained after the data transfer is complete. They can ensure that the client receives

the data from the expected server, and that the data sent by the server is not modified during transmission. However, they do not guarantee that the server transmits the data as originally published, and do not provide any methods to verify data that is read after transmission is complete. For example, a name server loading saved zone data upon restart cannot guarantee that the on-disk data has not been modified. For these reasons, it is preferable to secure the data itself.

Why not simply rely on DNSSEC, which provides certain data security guarantees? Certainly for zones that are signed, a recipient could validate all of the signed RRSets. Additionally, denial-of-existence records can prove that RRSets have not been added or removed. However, not all RRSets in a zone are signed. The design of DNSSEC stipulates that delegations (non-apex NS records) are not signed, and neither are any glue records. ZONEMD protects the integrity of delegation, glue, and other records that are not otherwise covered by DNSSEC. Furthermore, zones that employ NSEC3 with opt-out are susceptible to the removal or addition of names between the signed nodes. Whereas DNSSEC is primarily designed to protect consumers of DNS response messages, this protocol is designed to protect consumers of zones.

There are existing tools and protocols that provide data security, such as OpenPGP [<u>RFC4880</u>] and S/MIME [<u>RFC5751</u>]. In fact, the internic.net site publishes PGP signatures alongside the root zone and other files available there. However, this is a detached signature with no strong association to the corresponding zone file other than its timestamp. Non-detached signatures are, of course, possible, but these necessarily change the format of the file being distributed. That is, a zone signed with OpenPGP or S/MIME no longer looks like a DNS zone and could not directly be loaded into a name server. Once loaded the signature data is lost, so it does not survive further propagation.

It seems the desire for data security in DNS zones was envisioned as far back as 1997. [RFC2065] is an obsoleted specification of the first generation DNSSEC Security Extensions. It describes a zone transfer signature, aka AXFR SIG, which is similar to the technique proposed by this document. That is, it proposes ordering all (signed) RRSets in a zone, hashing their contents, and then signing the zone hash. The AXFR SIG is described only for use during zone transfers. It did not postulate the need to validate zone data distributed outside of the DNS. Furthermore, its successor, [RFC2535], omits the AXFR SIG, while at the same time introducing an IXFR SIG.

[Page 5]

## <u>1.2</u>. Design Overview

This document introduces a new Resource Record type designed to convey a message digest of the content of a zone. The digest is calculated at the time of zone publication. Ideally the zone is signed with DNSSEC to guarantee that any modifications of the digest can be detected. The procedures for digest calculation and DNSSEC signing are similar. Both require data to be processed in a welldefined order and format. In some cases it may be possible to perform DNSSEC signing and digest calculation in parallel.

The zone digest is designed to be used on zones that are relatively stable and have infrequent updates. As currently specified, the digest is re-calculated over the entire zone content each time. This specification does not provide an efficient mechanism for incremental updates of zone data. It is, however, extensible so that future schemes to support incremental zone digest algorithms (e.g. using Merkle trees) can be accommodated.

It is expected that verification of a zone digest would be implemented in name server software. That is, a name server can verify the zone data it was given and refuse to serve a zone which fails verification. For signed zones, the name server needs a trust anchor to perform DNSSEC validation. For signed non-root zones, the name server may need to send queries to validate a chain of trust. Digest verification could also be performed externally.

# 1.3. Use Cases

### **<u>1.3.1</u>**. Root Zone

The root zone [InterNIC] is one of the most widely distributed DNS zone on the Internet, served by more than 1000 separate instances [RootServers] at the time of this writing. Additionally, many organizations configure their own name servers to serve the root zone locally. Reasons for doing so include privacy and reduced access time. [RFC8806] describes one, but not the only, way to do this. As the root zone spreads beyond its traditional deployment boundaries, the need for verification of the completeness of the zone contents becomes increasingly important.

# **<u>1.3.2</u>**. Providers, Secondaries, and Anycast

Since its very early days, the developers of the DNS recognized the importance of secondary name servers and service diversity. However, they may not have anticipated the complexity of modern DNS service provisioning which can include multiple third-party providers and hundreds of anycast instances. Instead of a simple primary-to-

secondary zone distribution system, today it is possible to have multiple levels, multiple parties, and multiple protocols involved in the distribution of zone data. This complexity introduces new places for problems to arise. The zone digest protects the integrity of data that flows through such systems.

# **<u>1.3.3</u>**. Response Policy Zones

DNS Response Policy Zones is "a method of expressing DNS response policy information inside specially constructed DNS zones..." [RPZ]. A number of companies provide RPZ feeds, which can be consumed by name server and firewall products. Since these are zones, AXFR is often, but not necessarily used for transmission. While RPZ zones can certainly be signed with DNSSEC, the data is not queried directly, and would not be subject to DNSSEC validation.

## **<u>1.3.4</u>**. Centralized Zone Data Service

ICANN operates the Centralized Zone Data Service [CZDS], which is a repository of top-level domain zone files. Users request access to the system, and to individual zones, and are then able to download zone data for certain uses. Adding a zone digest to these would provide CZDS users with assurances that the data has not been modified. Note that ZONEMD could be added to CZDS zone data independently of the zone served by production name servers.

# **<u>1.3.5</u>**. General Purpose Comparison Check

Since the zone digest calculation does not depend on presentation format, it could be used to compare multiple copies of a zone received from different sources, or copies generated by different processes.

### **<u>1.4</u>**. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>BCP</u> <u>14</u> [<u>RFC2119</u>] [<u>RFC8174</u>] when, and only when, they appear in all capitals, as shown here.

# 2. The ZONEMD Resource Record

This section describes the ZONEMD Resource Record, including its fields, wire format, and presentation format. The Type value for the ZONEMD RR is 63. The ZONEMD RR is class independent. The RDATA of the resource record consists of four fields: Serial, Scheme, Hash Algorithm, and Digest.

A zone MAY contain multiple ZONEMD RRs to support algorithm agility [RFC7696] and rollovers. When multiple ZONEMD RRs are present, each must specify a unique Scheme and Hash Algorithm tuple. It is recommended that a zone include only one ZONEMD RR, unless the zone publisher is in the process of transitioning to a new Scheme or Hash Algorithm.

## 2.1. Non-apex ZONEMD Records

This specification utilizes ZONEMD RRs located at the zone apex. Non-apex ZONEMD RRs are not forbidden, but have no meaning in this specification. Non-apex ZONEMD RRs MUST NOT be used for verification.

During digest calculation, non-apex ZONEMD RRs are treated like any other RRs. They are digested as-is and the RR is not replaced by a placeholder RR.

Unless explicitly stated otherwise, "ZONEMD" always refers to apex records throughout this document.

# 2.2. ZONEMD RDATA Wire Format

The ZONEMD RDATA wire format is encoded as follows:

### 2.2.1. The Serial Field

The Serial field is a 32-bit unsigned integer in network order. It is equal to the serial number from the zone's SOA record ([RFC1035] section 3.3.13) for which the zone digest was generated.

The zone's serial number is included here in order to make DNS response messages of type ZONEMD meaningful. Without the serial number, a stand-alone ZONEMD digest has no association to any particular instance of a zone.

# 2.2.2. The Scheme Field

The Scheme field is an 8-bit unsigned integer that identifies the methods by which data is collated and presented as input to the hashing function.

At the time of this writing, SIMPLE, with value 1, is the only standardized Scheme defined for ZONEMD records. The Scheme registry is further described in <u>Section 5</u>.

Scheme values 240-254 are allocated for Private Use as described in [<u>RFC8126</u>].

### 2.2.3. The Hash Algorithm Field

The Hash Algorithm field is an 8-bit unsigned integer that identifies the cryptographic hash algorithm used to construct the digest.

At the time of this writing, SHA384, with value 1, is the only standardized Hash Algorithm defined for ZONEMD records. The Hash Algorithm registry is further described in <u>Section 5</u>.

Hash Algorithm values 240-254 are allocated for Private Use as described in [<u>RFC8126</u>].

## 2.2.4. The Digest Field

The Digest field is a variable-length sequence of octets containing the output of the hash algorithm. The Digest field must not be empty. <u>Section 3</u> describes how to calculate the digest for a zone. <u>Section 4</u> describes how to use the digest to verify the contents of a zone.

# 2.3. ZONEMD Presentation Format

The presentation format of the RDATA portion is as follows:

The Serial field is represented as an unsigned decimal integer.

The Scheme field is represented as an unsigned decimal integer.

The Hash Algorithm field is represented as an unsigned decimal integer.

The Digest is represented as a sequence of case-insensitive hexadecimal digits. Whitespace is allowed within the hexadecimal text.

## <u>2.4</u>. ZONEMD Example

The following example shows a ZONEMD RR.

example.com. 86400 IN ZONEMD 2018031500 1 1 ( FEBE3D4CE2EC2FFA4BA99D46CD69D6D29711E55217057BEE 7EB1A7B641A47BA7FED2DD5B97AE499FAFA4F22C6BD647DE )

## **3**. Calculating the Digest

### <u>3.1</u>. Add ZONEMD Placeholder

In preparation for calculating the zone digest, any existing ZONEMD records (and covering RRSIGs) at the zone apex are first deleted.

Prior to calculation of the digest, and prior to signing with DNSSEC, one or more placeholder ZONEMD records are added to the zone apex. This ensures that denial-of-existence (NSEC, NSEC3) records are created correctly if the zone is signed with DNSSEC. If placeholders are not added prior to signing, the later addition of ZONEMD records would also require updating the Type Bit Maps field of any apex NSEC/ NSEC3 RRs, which then invalidates the calculated digest value.

When multiple ZONEMD RRs are published in the zone, e.g., during an algorithm rollover, each must specify a unique Scheme and Hash Algorithm tuple.

It is recommended that the TTL of the ZONEMD record match the TTL of the SOA.

In the placeholder record, the Serial field is set to the current SOA Serial. The Scheme field is set to the value for the chosen collation scheme. The Hash Algorithm field is set to the value for the chosen hash algorithm. Since ZONEMD records are excluded from digest calculation, the value of the Digest field does not matter at this point in the process.

### <u>3.2</u>. Optionally Sign the Zone

Following addition of placeholder records, the zone may be signed with DNSSEC. Note that when the digest calculation is complete, and the ZONEMD record is updated, the signature(s) for the ZONEMD RRSet MUST be recalculated and updated as well. Therefore, the signer is not required to calculate a signature over the placeholder record at this step in the process, but it is harmless to do so.

## 3.3. Scheme-Specific Processing

At this time, only the SIMPLE collation scheme is defined. Additional schemes may be defined in future updates to this document.

# 3.3.1. The SIMPLE Scheme

For the SIMPLE scheme, the digest is calculated over the zone as a whole. This means that a change to a single RR in the zone requires iterating over all RRs in the zone to recalculate the digest. SIMPLE is a good choice for zones that are small and/or stable, but probably not good for zones that are large and/or dynamic.

Calculation of a zone digest REQUIRES RRs to be processed in a consistent format and ordering. Correct ordering depends on (1) ordering of owner names, (2) ordering of RRSets with the same owner name, and (3) ordering of RRs within an RRSet.

### 3.3.1.1. SIMPLE Scheme RR Format

This specification adopts DNSSEC's canonical on-the-wire RR format (without name compression) as specified in [<u>RFC4034</u>]:

RR(i) = owner | type | class | TTL | RDATA length | RDATA

where "|" denotes concatenation.

### 3.3.1.2. SIMPLE Scheme RR Ordering

This specification adopts DNSSEC's canonical ordering for names (<u>Section 6.1 of [RFC4034]</u>), and canonical ordering for RRs within an RRSet (<u>Section 6.3 of [RFC4034]</u>). It also adopts DNSSEC's canonical RR form (<u>Section 6.2 of [RFC4034]</u>).

However, since DNSSEC does not define a canonical ordering for RRSets having the same owner name, that ordering is defined here. For the purposes of calculating the zone digest, RRSets having the same owner name MUST be numerically ordered, in ascending order, by their numeric RR TYPE.

## 3.3.1.3. SIMPLE Scheme Inclusion/Exclusion Rules

When iterating over records in the zone, the following inclusion/ exclusion rules apply:

- o All records in the zone, including glue records, MUST be included.
- o Occluded data ([RFC5936] Section 3.5) MUST be included.

- o If there are duplicate RRs with equal owner, class, type, and RDATA, only one instance is included (<u>[RFC4034] Section 6.3</u>), and the duplicates MUST be omitted.
- o The placeholder ZONEMD RR(s) MUST NOT be included.
- o If the zone is signed, DNSSEC RRs MUST be included, except:
- o The RRSIG covering ZONEMD MUST NOT be included because the RRSIG will be updated after all digests have been calculated.

### 3.3.1.4. SIMPLE Scheme Digest Calculation

A zone digest using the SIMPLE scheme is calculated by concatenating all RRs in the zone, in the format described in <u>Section 3.3.1.1</u>, in the order described in <u>Section 3.3.1.2</u>, subject to the inclusion/ exclusion rules described in <u>Section 3.3.1.3</u>, and then applying the SHA-384 algorithm:

digest = SHA384( RR(1) | RR(2) | RR(3) | ... )

where "|" denotes concatenation.

# 3.4. Update ZONEMD RR

Once a zone digest has been calculated, the published ZONEMD record is finalised by inserting the digest into the placeholder ZONEMD. Repeat for each digest if multiple digests are to be published.

If the zone is signed with DNSSEC, the RRSIG record(s) covering the ZONEMD RRSet MUST then be added or updated. Because the ZONEMD placeholder was added prior to signing, the zone will already have the appropriate denial-of-existence (NSEC, NSEC3) records.

Some DNSSEC implementations (especially "online signing") might be designed such that the SOA serial number is updated whenever a new signature is made. To preserve the calculated digest, generation of an ZONEMD signature must not also result in a change to the SOA serial number. The ZONEMD RR and the matching SOA MUST be published at the same time.

# 4. Verifying Zone Digest

The recipient of a zone that has a ZONEMD RR can verify the zone by calculating the digest as follows. If multiple ZONEMD RRs are present in the zone, e.g., during an algorithm rollover, a match using any one of the recipient's supported Schemes and Hash Algorithms is sufficient to verify the zone.

- The verifier MUST first determine whether or not to expect DNSSEC records in the zone. This can be done by examining locally configured trust anchors, or querying for (and validating) DS RRs in the parent zone. For zones that are provably insecure, or if DNSSEC validation can not be performed, digest validation continues at step 4 below.
- For zones that are provably secure, the existence of the apex ZONEMD record MUST be verified. If the ZONEMD record provably does not exist, digest verification cannot be done. If the ZONEMD record does provably exist, but is not found in the zone, digest verification MUST NOT be considered successful.
- 3. For zones that are provably secure, the SOA and ZONEMD RRSets MUST have valid signatures, chaining up to a trust anchor. If DNSSEC validation of the SOA or ZONEMD records fails, digest verification MUST NOT be considered successful.
- 4. When multiple ZONEMD RRs are present, each must specify a unique Scheme and Hash Algorithm tuple. If the ZONEMD RRSet contains more than one RR with the same Scheme and Hash Algorithm, digest verification MUST NOT be considered successful.
- 5. Loop over all apex ZONEMD RRs and perform the following steps:
  - A. The SOA Serial field MUST exactly match the ZONEMD Serial field. If the fields do not match, digest verification MUST NOT be considered successful with this ZONEMD RR.
  - B. The Scheme field MUST be checked. If the verifier does not support the given scheme, it SHOULD report that the RR's digest could not be verified due to an unsupported scheme.
  - C. The Hash Algorithm field MUST be checked. If the verifier does not support the given hash algorithm, it SHOULD report that the RR's digest could not be verified due to an unsupported algorithm.
  - D. The zone digest is computed over the zone data as described in <u>Section 3.3</u>, using the Scheme and Hash Algorithm for the current ZONEMD RR.
  - E. The computed digest is compared to the received digest. If the two digest values match, verification is considered successful. Otherwise, verification MUST NOT be considered successful for this ZONEMD RR.

## 5. IANA Considerations

### **<u>5.1</u>**. ZONEMD RRtype

This document defines a new DNS RR type, ZONEMD, whose value 63 has been allocated by IANA from the "Resource Record (RR) TYPEs" subregistry of the "Domain Name System (DNS) Parameters" registry:

Type: ZONEMD

Value: 63

Meaning: Message Digest Over Zone Data

Reference: This document

### 5.2. ZONEMD Scheme

This document asks IANA to create a new "ZONEMD Scheme" registry with initial contents as follows:

Value	Description	Mnemonic	Status	Reference	
0     1     240-254	Reserved	RESERVED SIMPLE N/A	N/A   Mandatory     N/A	N/A   This   document   [ <u>RFC8126</u> ]	

Table 1: ZONEMD Scheme Registry

The IANA policy for assigning new values to the ZONEMD Scheme registry shall be Specification Required, as described in [<u>RFC8126</u>].

### 5.3. ZONEMD Hash Algorithm

This document asks IANA to create a new "ZONEMD Hash Algorithm" registry with initial contents as follows:

Wessels, et al. Expires March 1, 2021 [Page 14]

Table 2: ZONEMD Hash Algorithm Registry

The IANA policy for assigning new values to the ZONEMD Hash Algorithm registry shall be Specification Required, as described in [<u>RFC8126</u>].

## <u>6</u>. Security Considerations

# 6.1. Attacks Against the Zone Digest

The zone digest allows the receiver to verify that the zone contents haven't been modified since the zone was generated/published. Verification is strongest when the zone is also signed with DNSSEC. An attacker, whose goal is to modify zone content before it is used by the victim, may consider a number of different approaches.

The attacker might perform a downgrade attack to an unsigned zone. This is why <u>Section 4</u> talks about determining whether or not to expect DNSSEC signatures for the zone in step 1.

The attacker might perform a downgrade attack by removing one or more ZONEMD records. Such a removal is detectable only with DNSSEC validation and is why <u>Section 4</u> talks about checking denial-of-existence proofs in step 2 and signature validation in step 3.

The attacker might alter the Scheme, Hash Algorithm, or Digest fields of the ZONEMD record. Such modifications are detectable only with DNSSEC validation.

## 6.2. Attacks Utilizing ZONEMD Queries

Nothing in this specification prevents clients from making, and servers from responding to, ZONEMD queries. Servers SHOULD NOT calculate zone digests dynamically (for each query) as this can be used as a CPU resource exhaustion attack.

One might consider how well ZONEMD responses could be used in a distributed denial-of-service amplification attack. The ZONEMD RR is moderately sized, much like the DS RR. A single ZONEMD RR contributes approximately 40 to 65 octets to a DNS response, for

currently defined digest types. Certainly other RR types, such as DNSKEY, can result in larger amplification effects.

# <u>6.3</u>. Resilience and Fragility

ZONEMD can be used to detect incomplete or corrupted zone data prior to its use, thereby increasing resilience, but also introducing some fragility. Publishers and consumers of zones containing ZONEMD records should be aware of these tradeoffs. While the intention is to secure the zone data, misconfigurations or implementation bugs are generally indistinguishable from intentional tampering, and could lead to service failures when verification is performed automatically.

Zone publishers may want to deploy ZONEMD gradually, perhaps by utilizing one of the private use hash algorithms listed in <u>Section 5.3</u>. Similarly, recipients may want to initially configure verification failures only as a warning, and later as an error after gaining experience and confidence with the feature.

### 7. Performance Considerations

This section is provided to make zone publishers aware of the performance requirements and implications of including ZONEMD RRs in a zone.

### 7.1. SIMPLE SHA384

As mentioned previously, the SIMPLE scheme may not be appropriate for use in zones that are either large or highly dynamic. Zone publishers should carefully consider the use of ZONEMD in such zones, since it might cause consumers of zone data (e.g., secondary name servers) to expend resources on digest calculation. Furthermore, for such use cases, it is recommended that ZONEMD only be used when digest calculation time is significantly less than propagation times and update intervals.

The authors' implementation (Section 10.1) includes an option to record and report CPU usage of its operation. The software was used to generate digests for more than 800 TLD zones available from [CZDS]. The table below summarizes the the results for the SIMPLE scheme and SHA384 hash algorithm grouped by zone size. The Rate column is the mean amount of time per RR to calculate the digest, running on commodity hardware at the time of this writing.

+	-++
Zone Size (RRs)	Rate (msec/RR)
+	-++
10 - 99	0.00683
100 - 999	0.00551
1000 - 9999	0.00505
10000 - 99999	0.00602
100000 - 999999	0.00845
1000000 - 9999999	0.0108
10000000 - 99999999	0.0148
+	.++

For example, based on the above table, it takes approximately 0.13 seconds to calculate a SIMPLE SHA384 digest for a zone with 22,000 RRs, and about 2.5 seconds for a zone with 300,000 RRs.

These benchmarks attempt to emulate a worst-case scenario and take into account the time required to canonicalize the zone for processing. Each of the 800+ zones were measured three times, and then averaged, with a different random sorting of the input data prior to each measurement.

### 8. Privacy Considerations

This specification has no impact on user privacy.

### 9. Acknowledgments

The authors wish to thank David Blacka, Scott Hollenbeck, and Rick Wilhelm for providing feedback on early drafts of this document. Additionally, they thank Joe Abley, Mark Andrews, Ralph Dolmans, Richard Gibson, Olafur Gudmundsson, Bob Harold, Paul Hoffman, Evan Hunt, Shumon Huque, Tatuya Jinmei, Mike St. Johns, Burt Kaliski, Shane Kerr, Matt Larson, John Levine, Ed Lewis, Matt Pounsett, Mukund Sivaraman, Petr Spacek, Ondrej Sury, Willem Toorop, Florian Weimer, Tim Wicinksi, Wouter Wijngarrds, Paul Wouters, and other members of the dnsop working group for their input.

### **<u>10</u>**. Implementation Status

### <u>**10.1</u>**. Authors' Implementation</u>

The authors have an open source implementation in C, using the ldns library [<u>ldns-zone-digest</u>]. This implementation is able to perform the following functions:

o Read an input zone and output a zone with the ZONEMD placeholder.

- o Compute zone digest over signed zone and update the ZONEMD record.
- o Re-compute DNSSEC signature over the ZONEMD record.
- o Verify the zone digest from an input zone.

This implementation does not:

Perform DNSSEC validation of the ZONEMD record during verification.

#### **<u>10.2</u>**. Shane Kerr's Implementation

Shane Kerr wrote an implementation of this specification during the IETF 102 hackathon [ZoneDigestHackathon]. This implementation is in Python and is able to perform the following functions:

- o Read an input zone and output a zone with ZONEMD record.
- o Verify the zone digest from an input zone.
- o Output the ZONEMD record in its defined presentation format.

This implementation does not:

- o Re-compute DNSSEC signature over the ZONEMD record.
- o Perform DNSSEC validation of the ZONEMD record.

## 10.3. NIC Chile Labs Implementation

NIC Chile Labs wrote an implementation of this specification as part of "dns-tools" suite [<u>DnsTools</u>], which besides digesting, can also sign and verify zones. This implementation is in Go and is able to perform the following functions:

- o Compute zone digest over signed zone and update the ZONEMD record.
- o Verify the zone digest from an input zone.
- Perform DNSSEC validation of the ZONEMD record during verification.
- o Re-compute DNSSEC signature over the ZONEMD record.

Wessels, et al. Expires March 1, 2021 [Page 18]

# **<u>11</u>**. Change Log

RFC Editor: Please remove this section.

This section lists substantial changes to the document as it is being worked on.

From -00 to -01:

- o Removed requirement to sort by RR CLASS.
- o Added Kumari and Hardaker as coauthors.
- o Added Change Log section.
- o Minor clarifications and grammatical edits.

From -01 to -02:

- o Emphasize desire for data security over channel security.
- o Expanded motivation into its own subsection.
- o Removed discussion topic whether or not to include serial in ZONEMD.
- o Clarified that a zone's NS records always sort before the SOA record.
- o Clarified that all records in the zone must are digested, except as specified in the exclusion rules.
- o Added for discussion out-of-zone and occluded records.
- o Clarified that update of ZONEMD signature must not cause a serial number change.
- o Added persons to acknowledgments.

From -02 to -03:

- o Added recommendation to set ZONEMD TTL to SOA TTL.
- o Clarified that digest input uses uncompressed names.
- o Updated Implementations section.

Wessels, et al. Expires March 1, 2021 [Page 19]

- o Changed intended status from Standards Track to Experimental and added Scope of Experiment section.
- o Updated Motivation, Introduction, and Design Overview sections in response to working group discussion.
- o Gave ZONEMD digest types their own status, separate from DS digest types. Request IANA to create a registry.
- o Added Reserved field for future work supporting dynamic updates.
- o Be more rigorous about having just ONE ZONEMD record in the zone.
- o Expanded use cases.

From -03 to -04:

- o Added an appendix with example zones and digests.
- o Clarified that only apex ZONEMD RRs shall be processed.

From -04 to -05:

- o Made SHA384 the only supported ZONEMD digest type.
- o Disassociated ZONEMD digest types from DS digest types.
- o Updates to Introduction based on list feedback.
- o Changed "zone file" to "zone" everywhere.
- o Restored text about why ZONEMD has a Serial field.
- Clarified ordering of RRSets having same owner to be numerically ascending.
- o Clarified that all duplicate RRs (not just SOA) must be suppressed in digest calculation.
- o Clarified that the Reserved field must be set to zero and checked for zero in verification.
- o Clarified that occluded data must be included.
- Clarified procedure for verification, using temporary location for received digest.
- o Explained why Reserved field is 8-bits.

Wessels, et al. Expires March 1, 2021 [Page 20]

Inter	net-Draft	DNS Zone Digest	August 2020				
0	IANA Considerations se	ection now more specific.					
0	Added complex zone to	examples.					
0							
Fr	om -05 to -06:						
0	RR type code 63 was as	signed to ZONEMD by IANA.					
Fr	om -06 to -07:						
0	Fixed mistakes in ZONE	MD examples.					
0	Added private use Dige	est Type values 240-254.					
0	Clarified that Digest	field must not be empty.					
Fr	om -07 to <u>draft-ietf-dn</u>	<u>isop-dns-zone-digest-00</u> :					
0	Adopted by dnsop.						
0	Clarified further that	non-apex ZONEMD RRs have no	meaning.				
0	Changed "provably [un]	signed" to "provably [in]sec	ure".				
0	Allow multiple ZONEMD RRs to support algorithm agility/rollovers.						
0	o Describe verification when there are multiple ZONEMD RRs.						
Fr	om -00 to -01:						
0	Simplified requirement one match is sufficien	s around verifying multiple t.	digests. Any				
0	Updated implementation	notes.					
0	Both implementations p this document.	oroduce expected results on e	xamples given in				
Fr	om -01 to -02:						
0	Changed the name of th	e Reserved field to Paramete	r.				
0	Changed the name of Di	gest Type 1 from SHA384 to S	HA384-STABLE.				
0	The meaning of the Par	ameter field now depends on	Digest Type.				

Wessels, et al. Expires March 1, 2021 [Page 21]

- o No longer require Parameter field to be zero in verification.
- Updated a rule from earlier versions that said multiple ZONEMD RRs were not allowed.

From -02 to -03:

- Changed the name of Digest Type 1 from SHA384-STABLE to SHA384-SIMPLE.
- o Changed document status from Experimental to Standards Track.
- o Removed Scope of Experimentation section.

From -03 to -04:

- o Addressing WGLC feedback.
- o Changed from "Digest Type + Paramter" to "Scheme + Hash Algorithm". This should make it more obvious how ZONEMD can be expanded in the future with new schemes and hash algorithms, while sacrificing some of the flexibility that the Parameter was intended to provide.
- o Note: old RDATA fields: Serial, Digest Type, Parameter, Digest.
- o Note: new RDATA fields: Serial, Scheme, Hash Algorithm, Digest.
- o Add new IANA requirement for a Scheme registry.
- Rearranged some sections and separated scheme-specific aspects from general aspects of digest calculation.
- o When discussing multiple ZONEMD RRs, allow for Scheme, as well as Hash Algorithm, transition.
- o Added Performance Considerations section with some benchmarks.
- o Further clarifications about non-apex ZONEMD RRs.
- o Clarified inclusion rule for duplicate RRs.
- Removed or lowercased some inappropriately used <u>RFC 2119</u> key words.
- o Clarified that all ZONEMD RRs, even for unsupported hash algorithms, must be zeroized during digest calculation.

Wessels, et al. Expires March 1, 2021 [Page 22]

- o Added Resilience and Fragility to security considerations.
- Updated examples since changes in this version result in different hash values.

From -04 to -05:

- o Clarifications about non-apex and multiple ZONEMD RRs.
- o Clarifications about benchmark results.
- o Don't compute ZONEMD on-the-fly.
- o Specifciation Required for updates to ZONEMD protocol registries.
- o Other rewording based on WGLC feedback.
- o Updated RFC numbers for some references.
- o Use documentation IP addresses instead of loopback.
- o Updated examples in the appendix.

From -05 to -06:

- Per WG suggestion, no longer include any apex ZONEMD record in digest calculation.
- o Updated examples in the appendix.
- Clarified verification procedure by describing a loop over all ZONEMD RRs.

From -06 to -07:

o Added NIC Chile Labs implementation.

From -07 to -08:

o Update an author's affiliation.

- Clarified why placeholder RRs are still important (for NSEC/ NSEC3).
- o Moved subsection ("Order of RRSets Having the Same Owner Name") with single sentence paragraph up into parent section.

From -08 to -09:

Wessels, et al. Expires March 1, 2021 [Page 23]

- o Moved format, ordering, inclusion/exclusion into a sub section specific to the SIMPLE scheme.
- o Further clarified rules about multiple ZONEMD RRs (AD comments).
- Reworeded rules about processing of duplicate zone RRs (AD comments).
- Removed sentence about optional zeroing of digest prior to calculation (AD comments).
- o Other minor changes (AD comments).

# Appendix A. Example Zones With Digests

This appendix contains example zones with accurate ZONEMD records. These can be used to verify an implementation of the zone digest protocol.

# A.1. Simple EXAMPLE Zone

Here, the EXAMPLE zone contains an SOA record, NS and glue records, and a ZONEMD record.

example.	86400	IN	SOA	ns1 admin 2018031900 (
				1800 900 604800 86400 )

					2e20616c6c6f7765 )			

# A.3. EXAMPLE Zone with multiple digests

Here, the EXAMPLE zone contains multiple ZONEMD records. Since only one Scheme (SIMPLE) and one Hash Algorithm (SHA384) is defined at this time, this example utilizes additional ZONEMD records with Scheme and Hash Algorithm values in the private range (240-254). These additional private-range digests are not verifiable.
