Initializing a DNS Resolver with Priming Queries
draft-ietf-dnsop-resolver-priming-02

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on April 29, 2010.

Abstract

This document describes the initial queries a DNS resolver is supposed to emit to initialize its cache with a current NS RRSet for

the root zone as well as the necessary address information.

1. Introduction

Domain Name System (DNS) resolvers need a starting point to resolve queries. [\[RFC1034\]](#), [section 5.3.2](#), defines the SBELT structure in a full resolver as:

```
`a "safety belt" structure of the same form as SLIST, which is
initialized from a configuration file, and lists servers which
should be used when the resolver doesn't have any local
information to guide name server selection. The match count will
be -1 to indicate that no labels are known to match.''
```

[Section 5.3.3 of \[RFC1034\]](#) adds

```
`the usual choice is two of the root servers and two of the
servers for the host's domain''
```

Today's practice generally separates serving and resolving functionality, so the servers ``for the host's domain'' might no longer be an appropriate choice, even if they were only intended to resolve ``local'' names, especially since the SBELT structure does not distinguish between local and global information. In addition, DNS server implementations have for a long time been seeded with not only two but an exhaustive list of the root servers' addresses. This list is either supplied as a configuration file (root "hints", an excerpt of the DNS root zone) or even compiled into the software.

The list of root name servers has been rather stable over the last ten years. After the last four servers had been added and moved to their final (network) destinations in 1997, there have been only four address changes affecting the L (twice), J, and B servers. Research is available for B [[Mann2006](#)] and J [[BLKT2004](#)], which shows that several months or even years after the change had become effective, traffic is still received on the old addresses. Therefore, it is important that resolvers be able to cope with change, even without relying upon configuration updates to be applied by their operator.

Work by the ICANN SSAC and RSSAC committees, [[SSAC016](#)] and [[SSAC017](#)], aiming at adding AAAA RRs for the root name servers' names, deals with priming queries and so does a draft on DNSSEC Trust Anchor maintenance [[I-D.ietf-dnsop-dnssec-trust-anchor](#)]. However, it turned out that despite having been practiced for a long time, priming queries have not yet been documented as an important resolver feature.

The following sections cover parameters of both the priming query and the response to be sent by a root name server.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

[2. Priming Queries](#)

This document only deals with recursive name servers (recursive resolvers, resolvers) for the IN CLASS.

[2.1. Parameters of a Priming Query](#)

A priming query SHOULD use a QNAME of "." and a QTYPE of NS. The priming query MUST be sent over UDP ([section 6.1.3.2 of \[RFC1123\]](#)). The UDP source port SHOULD be randomly selected [[RFC5452](#)]. The RD bit MUST NOT be set. The resolver SHOULD also use EDNS0 [[RFC2671](#)] and announce and handle a reassembly size of at least 1024 octets [[RFC3226](#)].

[[Do we need a fallback strategy for EDNS unfriendly environments?]]

[2.2. Repeating Priming Queries](#)

A resolver SHOULD NOT originate a priming query more often than once per day (or whenever it starts). It SHOULD adhere to the TTL values given in the priming response. To avoid amnesia, the resolver MAY proactively re-prime before the old root NS RRSet expires from the cache, but only after 75 percent of the NS RRSet's TTL (or the A/AAAA RRSets' TTL, whichever is lower) have passed.

Should the priming query time out, the resolver should try another target address.

[2.3. Target Selection](#)

A resolver MUST select the target for a priming query randomly from the list of addresses (IPv4 and IPv6) available in its SBELT structure and it MUST ensure that all targets are selected with equal probability even upon startup. For resending the priming query to a different server the random selection SHOULD also be used.

[[Is it OK to send multiple priming queries to multiple targets in parallel?]]

2.4. DNSSEC with Priming Queries

The resolver SHOULD NOT set the DNSSEC OK [[RFC4033](#)] bit.

Discussion: Delegations in referral responses are not signed, so consequently the priming response is not validated, either. For that to work, the priming response would also have to be self-contained in that it would allow the resolver to not only validate the NS RRSets (with the root DNSKEY RRSets and the root NS RRSets' signatures), but also the A and AAAA RRSets. All this information cannot be guaranteed to be either present at the root name servers or fit into the priming response even with the largest feasible EDNS0 buffer size. In fact, in today's Internet, with the root name servers' names under "ROOT-SERVERS.NET.", this isn't even true for the top level domain involved. So, even though a poisoned priming response could drastically influence the resolver's operations, there is little a DNSSEC enhanced priming response could achieve without the whole validation chain. This would probably call for a different naming scheme (see section 6.1 of [[I-D.koch-dns-glue-clarifications](#)]).

3. Priming Responses

A root name server cannot distinguish a priming query from any other query for the root NS RRSets, except that QTYPE NS would not usually be part of the DNS resolution process.

3.1. Expected Properties of the Priming Response

The priming response can be expected to have an RCODE of NOERROR and the AA bit set. Also, there should be an NS RRSets in the answer section (since the NS RRSets originates from the root zone), an empty authority section (since the NS RRSets already appears in the answer section) and an additional section with A and AAAA RRSets for the root name servers pointed at by the NS RRSets. Resolver software SHOULD NOT expect a fixed number of 13 NS RRs, since "internal" root server setups in split DNS configurations might use a different number of servers. Resolver software SHOULD warn the operator about any change in the number or names of name servers compared to the SBELT information.

3.2. Use of the Priming Response

A resolver MAY use the priming response as it would use any other data fed to its cache. However, it SHOULD NOT use the SBELT information directly in any responses it hands out.

[[Is there any special consideration needed for those cases where

someone managed to cause a signed root NS RRSets being fed into the cache?]]

3.3. Completeness of the Response

For an EDNS response, a resolver SHOULD consider the address information found in the additional section complete for any particular server that appears at all. In other words: if the additional section only has an A RRSets for a server, the resolver SHOULD assume that no AAAA RRSets exists. To ensure equal availability the A and AAAA RRSets should have identical TTL values at the authoritative source. [[There might still be some degenerate cases of response sizes between 512 and 1024.]]

[[If the resolver did not announce a reassembly size larger than 512 octets, this assumption is invalid. How to acquire the remaining address RRSets is TBD. Simple re-issuing of the priming query does not help with those root name servers that respond with a fixed order of addresses in the additional section.]]

4. Requirements for Root Name Servers and the Root Zone

The operational requirements for root name servers are described in [[RFC2870](#)]. This section specifies additional guidance for the configuration of and software deployed at the root name servers.

All DNS root name servers need to be able to provide for all addresses of all root name servers. This can easily be achieved by making all root name servers authoritative for the zone containing the servers' names.

[[At the time of writing, all but one root name server were authoritative for ROOT-SERVERS.NET., even though only a subset received an official delegation.]]

If the response packet does not provide for more than 512 octets due to lack of EDNS0 support, A RRSets SHOULD be given preference over AAAA RRSets when filling the additional section.

[[EDNS0 is used as an indication of AAAA understanding on the side of the client. What to do with small payload sizes indicated by EDNS0 is open to discussion. At the time of writing, some root name servers will fill the additional section with all available A RRSets, only adding some AAAA RRSets, when queried over IPv4 without EDNS0. Other servers will deliver more AAAA RRSets, therefore withholding some A RRSets completely [[RFC4472](#)].]]

[[Do the TTLs for the root NS RRSset and address RRSets in the root and the ROOT-SERVERS.NET. zones need to be aligned? In real life responses, the address RRSset's TTL values vary by implementation.]]

5. Security Considerations

This document deals with priming a DNS resolver's cache. The usual DNS caveats apply. Use of DNSSEC with priming queries is discussed in [section 2.4](#).

Spoofing a response to a priming query can be used to redirect all queries originating from a victim resolver, therefore any difference between the initial SBELT list and the priming response SHOULD be brought to the operators' attention. There is also a chance that the random target selection chooses the address of a retired root name server. Operational measures to prevent reuse of these addresses are out of the scope of this document.

6. IANA Considerations

This document does not propose any new IANA registry nor does it ask for any allocation from an existing IANA registry.

However, this document deals with requirements for the root zone and root server operations.

[[Any recommendation on the "." NS RRSset TTL or the TTLs of the respective A and/or AAAA RRSets would go here.]]

[[This section needs more work.]]

Appendix A. Document Revision History

This section is to be removed should the draft be published.

\$Id: [draft-ietf-dnsop-resolver-priming.xml](#),v 1.4 2009/10/26 20:18:33
pk Exp \$

A.1. -02 WG Document

Revived. Changed use of DNSSEC OK in the priming query as per the WG discussion.

A.2. -01 WG Document

Revived with minor edits. Open issues marked [[]].

A.3. -00 WG Document

Reposted as WG document with minor edits.

Added re-priming proposal and A/AAAA TTL considerations.

A.4. Initial Document

First draft
