# Distributed Denial-of-Service Open Threat Signaling (DOTS) Telemetry draft-ietf-dots-telemetry-08

### Abstract

This document aims to enrich DOTS signal channel protocol with various telemetry attributes allowing optimal Distributed Denial-of-Service attack mitigation. It specifies the normal traffic baseline and attack traffic telemetry attributes a DOTS client can convey to its DOTS server in the mitigation request, the mitigation status telemetry attributes a DOTS server can communicate to a DOTS client, and the mitigation efficacy telemetry attributes a DOTS client can communicate to a DOTS server. The telemetry attributes can assist the mitigator to choose the DDoS mitigation techniques and perform optimal DDoS attack mitigation.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of <u>BCP 78</u> and <u>BCP 79</u>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <u>https://datatracker.ietf.org/drafts/current/</u>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 9, 2020.

### **<u>1</u>**. Introduction

Distributed Denial of Service (DDoS) attacks have become more sophisticated. IT organizations and service providers are facing DDoS attacks that fall into two broad categories:

 Network/Transport layer attacks target the victim's infrastructure. These attacks are not necessarily aimed at taking down the actual delivered services, but rather to eliminate various network elements (routers, switches, firewalls, transit links, and so on) from serving legitimate users traffic.

The main method of such attacks is to send a large volume or high packet per second (pps) of traffic toward the victim's infrastructure. Typically, attack volumes may vary from a few 100 Mbps to 100s of Gbps or even Tbps. Attacks are commonly carried out leveraging botnets and attack reflectors for amplification attacks such as NTP (Network Time Protocol), DNS

Boucadair, et al. Expires November 9, 2020 [Page 3]

(Domain Name System), SNMP (Simple Network Management Protocol), or SSDP (Simple Service Discovery Protocol).

 Application layer attacks target various applications. Typical examples include attacks against HTTP/HTTPS, DNS, SIP (Session Initiation Protocol), or SMTP (Simple Mail Transfer Protocol). However, all applications with their port numbers open at network edges can be attractive attack targets.

Application layer attacks are considered more complex and hard to categorize, therefore harder to detect and mitigate efficiently.

To compound the problem, attackers also leverage multi-vectored attacks. These attacks are assembled from dynamic attack vectors (Network/Application) and tactics. As such, multiple attack vectors formed by multiple attack types and volumes are launched simultaneously towards a victim. Multi-vector attacks are harder to detect and defend. Multiple and simultaneous mitigation techniques are needed to defeat such attack campaigns. It is also common for attackers to change attack vectors right after a successful mitigation, burdening their opponents with changing their defense methods.

The ultimate conclusion derived from these real scenarios is that modern attacks detection and mitigation are most certainly complicated and highly convoluted tasks. They demand a comprehensive knowledge of the attack attributes, the targeted normal behavior (including, normal traffic patterns), as well as the attacker's ongoing and past actions. Even more challenging, retrieving all the analytics needed for detecting these attacks is not simple to obtain with the industry's current capabilities.

The DOTS signal channel protocol [I-D.ietf-dots-signal-channel] is used to carry information about a network resource or a network (or a part thereof) that is under a DDoS attack. Such information is sent by a DOTS client to one or multiple DOTS servers so that appropriate mitigation actions are undertaken on traffic deemed suspicious. Various use cases are discussed in [I-D.ietf-dots-use-cases].

Typically, DOTS clients can be integrated within a DDoS attack detector, or network and security elements that have been actively engaged with ongoing attacks. The DOTS client mitigation environment determines that it is no longer possible or practical for it to handle these attacks. This can be due to a lack of resources or security capabilities, as derived from the complexities and the intensity of these attacks. In this circumstance, the DOTS client has invaluable knowledge about the actual attacks that need to be handled by its DOTS server(s). By enabling the DOTS client to share

Boucadair, et al. Expires November 9, 2020 [Page 4]

Internet-Draft

this comprehensive knowledge of an ongoing attack under specific circumstances, the DOTS server can drastically increase its ability to accomplish successful mitigation. While the attack is being handled by the DOTS server associated mitigation resources, the DOTS server has the knowledge about the ongoing attack mitigation. The DOTS server can share this information with the DOTS client so that the client can better assess and evaluate the actual mitigation realized.

DOTS clients can send mitigation hints derived from attack details to DOTS servers, with the full understanding that the DOTS server may ignore mitigation hints, as described in [<u>RFC8612</u>] (Gen-004). Mitigation hints will be transmitted across the DOTS signal channel, as the data channel may not be functional during an attack. How a DOTS server is handling normal and attack traffic attributes, and mitigation hints is implementation-specific.

Both DOTS client and server can benefit this information by presenting various information in relevant management, reporting, and portal systems.

This document defines DOTS telemetry attributes that can be conveyed by DOTS clients to DOTS servers, and vice versa. The DOTS telemetry attributes are not mandatory fields. Nevertheless, when DOTS telemetry attributes are available to a DOTS agent, and absent any policy, it can signal the attributes in order to optimize the overall mitigation service provisioned using DOTS. Some of the DOTS telemetry data is not shared during an attack time.

## 2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>BCP</u> <u>14</u> [<u>RFC2119</u>][RFC8174] when, and only when, they appear in all capitals, as shown here.

The reader should be familiar with the terms defined in [RFC8612].

"DOTS Telemetry" is defined as the collection of attributes that are used to characterize normal traffic baseline, attacks and their mitigation measures, and any related information that may help in enforcing countermeasures. The DOTS Telemetry is an optional set of attributes that can be signaled in the DOTS signal channel protocol.

The meaning of the symbols in YANG tree diagrams is defined in [<u>RFC8340</u>].

Boucadair, et al. Expires November 9, 2020 [Page 5]

## 3. DOTS Telemetry: Overview and Purpose

When signaling a mitigation request, it is most certainly beneficial for DOTS clients to signal to DOTS servers any knowledge regarding ongoing attacks. This can happen in cases where DOTS clients are asking DOTS servers for support in defending against attacks that they have already detected and/or mitigated. These actions taken by DOTS clients are referred to as "signaling the DOTS Telemetry".

If attacks are already detected and categorized within a DOTS client domain, the DOTS server, and its associated mitigation services, can proactively benefit this information and optimize the overall service delivery. It is important to note that DOTS clients and servers detection and mitigation approaches can be different, and can potentially outcome different results and attack classifications. The DDoS mitigation service treats the ongoing attack details received from DOTS clients as hints and cannot completely rely or trust the attack details conveyed by DOTS clients.

A basic requirement of security operation teams is to be aware and get visibility into the attacks they need to handle. The DOTS server security operation teams benefit from the DOTS telemetry, especially from the reports of ongoing attacks. Even if some mitigation can be automated, operational teams can use the DOTS telemetry to be prepared for attack mitigation and to assign the correct resources (operation staff, networking and mitigation) for the specific service. Similarly, security operation personnel at the DOTS client side ask for feedback about their requests for protection. Therefore, it is valuable for DOTS servers to share DOTS telemetry with DOTS clients.

Mutual sharing of information is thus crucial for "closing the mitigation loop" between DOTS clients and servers. For the server side team, it is important to realize that the same attacks that the DOTS server's mitigation resources are seeing are those that a DOTS client is asking to mitigate. For the DOTS client side team, it is important to realize that the DOTS clients receive the required service. For example, understanding that "I asked for mitigation of two attacks and my DOTS server detects and mitigates only one...". Cases of inconsistency in attack classification between DOTS clients and servers can be highlighted, and maybe handled, using the DOTS telemetry attributes.

In addition, management and orchestration systems, at both DOTS client and server sides, can use DOTS telemetry as a feedback to automate various control and management activities derived from signaled telemetry information.

Boucadair, et al. Expires November 9, 2020 [Page 6]

#### DOTS Telemetry

If the DOTS server's mitigation resources have the capabilities to facilitate the DOTS telemetry, the DOTS server adapts its protection strategy and activates the required countermeasures immediately (automation enabled) for the sake of optimized attack mitigation decisions and actions.

DOTS telemetry can also be used to tune the DDoS mitigators with the correct state of an attack. During the last few years, DDoS attack detection technologies have evolved from threshold-based detection (that is, cases when all or specific parts of traffic cross a predefined threshold for a certain period of time is considered as an attack) to an "anomaly detection" approach. For the latter, it is required to maintain rigorous learning of "normal" behavior and where an "anomaly" (or an attack) is identified and categorized based on the knowledge about the normal behavior and a deviation from this normal behavior. Machine learning approaches are used such that the actual traffic thresholds are automatically calculated by learning the protected entity normal traffic behavior during idle time. The normal traffic baseline". An attack is detected when the victim's actual traffic is deviating from this normal baseline.

In addition, subsequent activities toward mitigating an attack are much more challenging. The ability to distinguish legitimate traffic from attacker traffic on a per packet basis is complex. For example, a packet may look "legitimate" and no attack signature can be identified. The anomaly can be identified only after detailed statistical analysis. DDoS attack mitigators use the normal baseline during the mitigation of an attack to identify and categorize the expected appearance of a specific traffic pattern. Particularly, the mitigators use the normal baseline to recognize the "level of normality" needs to be achieved during the various mitigation process.

Normal baseline calculation is performed based on continuous learning of the normal behavior of the protected entities. The minimum learning period varies from hours to days and even weeks, depending on the protected application behavior. The baseline cannot be learned during active attacks because attack conditions do not characterize the protected entities' normal behavior.

If the DOTS client has calculated the normal baseline of its protected entities, signaling such information to the DOTS server along with the attack traffic levels is significantly valuable. The DOTS server benefits from this telemetry by tuning its mitigation resources with the DOTS client's normal baseline. The DOTS server mitigators use the baseline to familiarize themselves with the attack victim's normal behavior and target the baseline as the level of

Boucadair, et al. Expires November 9, 2020 [Page 7]

normality they need to achieve. Fed with this inforamtion, the overall mitigation performances is expected to be improved in terms of time to mitigate, accuracy, false-negative, and false-positive.

Mitigation of attacks without having certain knowledge of normal traffic can be inaccurate at best. This is especially true for recursive signaling (see Section 3.2.3 in [I-D.ietf-dots-use-cases]). In addition, the highly diverse types of use-cases where DOTS clients are integrated also emphasize the need for knowledge of each DOTS client domain behavior. Consequently, common global thresholds for attack detection practically cannot be realized. Each DOTS client domain can have its own levels of traffic and normal behavior. Without facilitating normal baseline signaling, it may be very difficult for DOTS servers in some cases to detect and mitigate the attacks accurately:

It is important to emphasize that it is practically impossible for the DOTS server's mitigators to calculate the normal baseline in cases where they do not have any knowledge of the traffic beforehand.

In addition, baseline learning requires a period of time that cannot be afforded during active attack.

Of course, this information can provided using out-of-band mechanisms or manual configuration at the risk to maintain inaccurate information as the network evolves and "normal" patterns change. The use of a dynamic and collaborative means between the DOTS client and server to identify and share key parameters for the sake of efficient DDoS protection is valuable.

During a high volume attack, DOTS client pipes can be totally saturated. DOTS clients ask their DOTS servers to handle the attack upstream so that DOTS client pipes return to a reasonable load level (normal pattern, ideally). At this point, it is essential to ensure that the mitigator does not overwhelm the DOTS client pipes by sending back "clean traffic", or what it believes is "clean". This can happen when the mitigator has not managed to detect and mitigate all the attacks launched towards the DOTS client domain. In this case, it can be valuable to DOTS clients to signal to DOTS servers the "total pipe capacity", which is the level of traffic the DOTS client domain can absorb from its upstream network. Dynamic updates of the condition of pipes between DOTS agents while they are under a DDoS attack is essential (e.g., where multiple DOTS clients share the same physical connectivity pipes). It is important to note that the term "pipe" noted here does not necessary represent physical pipe, but rather represents the maximum level of traffic that the DOTS client domain can receive. The DOTS server should activate other

Boucadair, et al. Expires November 9, 2020 [Page 8]

mechanisms to ensure it does not allow the DOTS client domain's pipes to be saturated unintentionally. The rate-limit action defined in [<u>I-D.ietf-dots-data-channel</u>] is a reasonable candidate to achieve this objective; the DOTS client can ask for the type(s) of traffic (such as ICMP, UDP, TCP port number 80) it prefers to limit. The rate-limit action can be controlled via the signal-channel [<u>I-D.ietf-dots-signal-filter-control</u>] even when the pipe is overwhelmed.

To summarize:

Timely and effective signaling of up-to-date DDoS telemetry to all elements involved in the mitigation process is essential and absolutely improves the overall DDoS mitigation service effectiveness. Bi-directional feedback between DOTS agents is required for an increased awareness of each party, supporting superior and highly efficient attack mitigation service.

## **<u>4</u>**. Generic Considerations

## **<u>4.1</u>**. DOTS Client Identification

Following the rules in [<u>I-D.ietf-dots-signal-channel</u>], a unique identifier is generated by a DOTS client to prevent request collisions ('cuid').

As a reminder, [<u>I-D.ietf-dots-signal-channel</u>] forbids 'cuid' to be returned in a response message body.

#### 4.2. DOTS Gateways

DOTS gateways may be located between DOTS clients and servers. The considerations elaborated in [<u>I-D.ietf-dots-signal-channel</u>] must be followed. In particular, 'cdid' attribute is used to unambiguously identify a DOTS client domain.

As a reminder, [<u>I-D.ietf-dots-signal-channel</u>] forbids 'cdid' (if present) to be returned in a response message body.

#### 4.3. Empty URI Paths

Uri-Path parameters and attributes with empty values MUST NOT be present in a request and render an entire message invalid.

Boucadair, et al. Expires November 9, 2020 [Page 9]

## 4.4. Controlling Configuration Data

The DOTS server follows the same considerations discussed in Section of 4.5.3 of [I-D.ietf-dots-signal-channel] for managing DOTS telemetry configuration freshness and notification. Likewise, a DOTS client may control the selection of configuration and nonconfiguration data nodes when sending a GET request by means of the 'c' Uri-Query option and following the procedure specified in Section of 4.4.2 of [I-D.ietf-dots-signal-channel]. These considerations are not re-iterated in the following sections.

## 4.5. Block-wise Transfer

DOTS clients can use Block-wise transfer [<u>RFC7959</u>] with the recommendation detailed in Section 4.4.2 of [<u>I-D.ietf-dots-signal-channel</u>] to control the size of a response when the data to be returned does not fit within a single datagram.

DOTS clients can also use Block1 Option in a PUT request (see <u>Section 2.5 of [RFC7959]</u>) to initiate large transfers, but these Block1 transfers will fail if the inbound "pipe" is running full, so consideration needs to be made to try to fit this PUT into a single transfer, or to separate out the PUT into several discrete PUTs where each of them fits into a single packet.

Block3 and Block 4 options that are similar to the CoAP Block1 and Block2 options, but enable faster transmissions of big blocks of data with less packet interchanges, are defined in [<u>I-D.bosh-core-new-block</u>]. DOTS implementations can consider the use of Block3 and Block 4 options.

## **<u>4.6</u>**. DOTS Multi-homing Considerations

Multi-homed DOTS clients are assumed to follow the recommendations in [I-D.ietf-dots-multihoming] to select which DOTS server to contact and which IP prefixes to include in a telemetry message to a given peer DOTS server. For example, if each upstream network exposes a DOTS server and the DOTS client maintains DOTS channels with all of them, only the information related to prefixes assigned by an upstream network to the DOTS client domain will be signaled via the DOTS channel established with the DOTS server of that upstream network. Considerations related to whether (and how) a DOTS client gleans some telemetry information (e.g., attack details) it receives from a first DOTS server and share it with a second DOTS server are implementation and deployment-specific.

Boucadair, et al. Expires November 9, 2020 [Page 10]

### 4.7. YANG Considerations

Telemetry messages exchanged between DOTS agents are serialized using Concise Binary Object Representation (CBOR). CBOR-encoded payloads are used to carry signal channel-specific payload messages which convey request parameters and response information such as errors [I-D.ietf-dots-signal-channel].

This document specifies a YANG module for representing DOTS telemetry message types (<u>Section 9.1</u>). All parameters in the payload of the DOTS signal channel are mapped to CBOR types as specified in <u>Section 10</u>.

The DOTS telemetry module (Section 9.1) is not intended to be used via NETCONF/RESTCONF for DOTS server management purposes. It serves only to provide a data model and encoding, but not a management data model. DOTS servers are allowed to update the non-configurable 'ro' entities in the responses of DOTS telemetry messages.

The DOTS telemetry module (<u>Section 9.1</u>) uses "enumerations" rather than "identities" to define units, samples, and intervals because otherwise the namespace identifier "ietf-dots-telemetry" must be included when a telemetry attribute is included (e.g., in a mitigation efficacy update). The use of "identities" is thus suboptimal from a message compactness standpoint.

## <u>4.8</u>. A Note About Examples

Examples are provided for illustration purposes. The document does not aim to provide a comprehensive list of message examples.

The authoritative reference for validating telemetry messages is the YANG module (<u>Section 9.1</u>) and the mapping table established in <u>Section 10</u>.

### **<u>5</u>**. Telemetry Operation Paths

As discussed in [<u>I-D.ietf-dots-signal-channel</u>], each DOTS operation is indicated by a path-suffix that indicates the intended operation. The operation path is appended to the path-prefix to form the URI used with a CoAP request to perform the desired DOTS operation. The following telemetry path-suffixes are defined (Table 1):

Boucadair, et al. Expires November 9, 2020 [Page 11]

+   Operation	Operation Path	Details
+   Telemetry Setup   Telemetry +	/tm-setup   /tm	Section 6   Section 7

Table 1: DOTS Telemetry Operations

Consequently, the "ietf-dots-telemetry" YANG module defined in <u>Section 9.1</u> augments the "ietf-dots-signal" with two new message types called "telemetry-setup" and "telemetry". The tree structure is shown in Figure 1 (more details are provided in the following sections about the exact structure of "telemetry-setup" and "telemetry" message types).

```
augment /ietf-signal:dots-signal/ietf-signal:message-type:
 +--:(telemetry-setup) {dots-telemetry}?
 . . .
      +--rw (setup-type)?
 +--:(telemetry-config)
  | ...
 +--:(pipe)
 | ...
          +--:(baseline)
 . . .
 +--:(telemetry) {dots-telemetry}?
    . . .
```

Figure 1: New DOTS Message Types (YANG Tree Structure)

### **<u>6</u>**. DOTS Telemetry Setup Configuration

In reference to Figure 1, a DOTS telemetry setup message MUST include only telemetry-related configuration parameters (<u>Section 6.1</u>) or information about DOTS client domain pipe capacity (<u>Section 6.2</u>) or telemetry traffic baseline (<u>Section 6.3</u>). As such, requests that include a mix of telemetry configuration, pipe capacity, or traffic baseline MUST be rejected by DOTS servers with a 4.00 (Bad Request).

A DOTS client can reset all installed DOTS telemetry setup configuration data following the considerations detailed in <u>Section 6.4</u>.

A DOTS server may detect conflicts when processing requests related to DOTS client domain pipe capacity or telemetry traffic baseline

Boucadair, et al. Expires November 9, 2020 [Page 12]

with requests from other DOTS clients of the same DOTS client domain. More details are included in <u>Section 6.5</u>.

Telemetry setup configuration is bound to a DOTS client domain. DOTS servers MUST NOT expect DOTS clients to send regular requests to refresh the telemetry setup configuration. Any available telemetry setup configuration has a validity timeout of the DOTS association with a DOTS client domain. DOTS servers MUST NOT reset 'tsid' because a session failed with a DOTS client. DOTS clients update their telemetry setup configuration upon change of a parameter that may impact attack mitigation.

DOTS telemetry setup configuration request and response messages are marked as Confirmable messages.

## <u>6.1</u>. Telemetry Configuration

A DOTS client can negotiate with its server(s) a set of telemetry configuration parameters to be used for telemetry. Such parameters include:

- o Percentile-related measurement parameters
- o Measurement units
- o Acceptable percentile values
- o Telemetry notification interval
- o Acceptable Server-originated telemetry

<u>Section 11.3 of [RFC2330]</u> includes more details about computing percentiles.

### <u>6.1.1</u>. Retrieve Current DOTS Telemetry Configuration

A GET request is used to obtain acceptable and current telemetry configuration parameters on the DOTS server. This request may include a 'cdid' Path-URI when the request is relayed by a DOTS gateway. An example of such request is depicted in Figure 2.

Boucadair, et al. Expires November 9, 2020 [Page 13]

Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"

Figure 2: GET to Retrieve Current and Acceptable DOTS Telemetry Configuration

Upon receipt of such request, the DOTS server replies with a 2.05 (Content) response that conveys the current and telemetry parameters acceptable by the DOTS server. The tree structure of the response message body is provided in Figure 3. Note that the response also includes any pipe (Section 6.2) and baseline information (Section 6.3) maintained by the DOTS server for this DOTS client.

DOTS servers that support the capability of sending telemetry information to DOTS clients prior or during a mitigation (<u>Section 8.2</u>) sets 'server-originated-telemetry' under 'max-configvalues' to 'true' ('false' is used otherwise). If 'serveroriginated-telemetry' is not present in a response, this is equivalent to receiving a request with 'server-originated-telemetry' set to 'false'.

Boucadair, et al. Expires November 9, 2020 [Page 14]

Figure 3: Telemetry Configuration Tree Structure

Boucadair, et al. Expires November 9, 2020 [Page 15]

When both 'min-config-values' and 'max-config-values' attributes are present, the values carried in 'max-config-values' attributes MUST be greater or equal to their counterpart in 'min-config-values' attributes.

## 6.1.2. Convey DOTS Telemetry Configuration

PUT request is used to convey the configuration parameters for the telemetry data (e.g., low, mid, or high percentile values). For example, a DOTS client may contact its DOTS server to change the default percentile values used as baseline for telemetry data. Figure 3 lists the attributes that can be set by a DOTS client in such PUT request. An example of a DOTS client that modifies all percentile reference values is shown in Figure 4.

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"
Content-Format: "application/dots+cbor"
{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "current-config": {
          "low-percentile": "5.00",
          "mid-percentile": "65.00",
          "high-percentile": "95.00"
        }
      }
    1
 }
}
      Figure 4: PUT to Convey the DOTS Telemetry Configuration
```

'cuid' is a mandatory Uri-Path parameter for PUT requests.

The following additional Uri-Path parameter is defined:

tsid: Telemetry Setup Identifier is an identifier for the DOTS
 telemetry setup configuration data represented as an integer.
 This identifier MUST be generated by DOTS clients. 'tsid'
 values MUST increase monotonically (when a new PUT is generated

Boucadair, et al. Expires November 9, 2020 [Page 16]

by a DOTS client to convey new configuration parameters for the telemetry).

The procedure specified in Section 4.4.1 of [<u>I-D.ietf-dots-signal-channel</u>] MUST be followed for 'tsid' rollover.

This is a mandatory attribute.

'cuid' and 'tsid' MUST NOT appear in the PUT request message body.

At least one configurable attribute MUST be present in the PUT request.

The PUT request with a higher numeric 'tsid' value overrides the DOTS telemetry configuration data installed by a PUT request with a lower numeric 'tsid' value. To avoid maintaining a long list of 'tsid' requests for requests carrying telemetry configuration data from a DOTS client, the lower numeric 'tsid' MUST be automatically deleted and no longer be available at the DOTS server.

The DOTS server indicates the result of processing the PUT request using the following response codes:

- o If the request is missing a mandatory attribute, does not include 'cuid' or 'tsid' Uri-Path parameters, or contains one or more invalid or unknown parameters, 4.00 (Bad Request) MUST be returned in the response.
- o If the DOTS server does not find the 'tsid' parameter value conveyed in the PUT request in its configuration data and if the DOTS server has accepted the configuration parameters, then a response code 2.01 (Created) MUST be returned in the response.
- o If the DOTS server finds the 'tsid' parameter value conveyed in the PUT request in its configuration data and if the DOTS server has accepted the updated configuration parameters, 2.04 (Changed) MUST be returned in the response.
- o If any of the enclosed configurable attribute values are not acceptable to the DOTS server (<u>Section 6.1.1</u>), 4.22 (Unprocessable Entity) MUST be returned in the response.

The DOTS client may re-try and send the PUT request with updated attribute values acceptable to the DOTS server.

By default, low percentile (10th percentile), mid percentile (50th percentile), high percentile (90th percentile), and peak (100th

Boucadair, et al. Expires November 9, 2020 [Page 17]

percentile) values are used to represent telemetry data. Nevertheless, a DOTS client can disable some percentile types (low, mid, high). In particular, setting 'low-percentile' to '0.00' indicates that the DOTS client is not interested in receiving lowpercentiles. Likewise, setting 'mid-percentile' (or 'highpercentile') to the same value as 'low-percentile' (or 'midpercentile') indicates that the DOTS client is not interested in receiving mid-percentiles (or high-percentiles). For example, a DOTS client can send the request depicted in Figure 5 to inform the server that it is interested in receiving only high-percentiles. This assumes that the client will only use that percentile type when sharing telemetry data with the server.

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=569"
Content-Format: "application/dots+cbor"
```

Figure 5: PUT to Disable Low- and Mid-Percentiles

DOTS clients can also configure the unit type(s) to be used for traffic-related telemetry data. Typically, the supported unit types are: packets per second, bits per second, and bytes per second.

DOTS clients that are interested to receive pre- or ongoing mitigation telemetry (pre-or-ongoing-mitigation) information from a DOTS server (<u>Section 8.2</u>) MUST set 'server-originated-telemetry' to 'true'. If 'server-originated-telemetry' is not present in a PUT request, this is equivalent to receiving a request with 'serveroriginated-telemetry' set to 'false'. An example of a request to

Boucadair, et al. Expires November 9, 2020 [Page 18]

```
enable pre-or-ongoing-mitigation telemetry from DOTS servers is shown
in Figure 6.
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=569"
Content-Format: "application/dots+cbor"
{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "current-config": {
          "server-originated-telemetry": true
        }
      }
   ]
 }
}
```

Figure 6: PUT to Enable Pre-or-ongoing-mitigation Telemetry from the DOTS server

## 6.1.3. Retrieve Installed DOTS Telemetry Configuration

A DOTS client may issue a GET message with 'tsid' Uri-Path parameter to retrieve the current DOTS telemetry configuration. An example of such request is depicted in Figure 7.

Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"

Figure 7: GET to Retrieve Current DOTS Telemetry Configuration

If the DOTS server does not find the 'tsid' Uri-Path value conveyed in the GET request in its configuration data for the requesting DOTS client, it MUST respond with a 4.04 (Not Found) error response code.

Boucadair, et al. Expires November 9, 2020 [Page 19]

## 6.1.4. Delete DOTS Telemetry Configuration

A DELETE request is used to delete the installed DOTS telemetry configuration data (Figure 8). 'cuid' and 'tsid' are mandatory Uri-Path parameters for such DELETE requests.

```
Header: DELETE (Code=0.04)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"
```

Figure 8: Delete Telemetry Configuration

The DOTS server resets the DOTS telemetry configuration back to the default values and acknowledges a DOTS client's request to remove the DOTS telemetry configuration using 2.02 (Deleted) response code. A 2.02 (Deleted) Response Code is returned even if the 'tsid' parameter value conveyed in the DELETE request does not exist in its configuration data before the request.

<u>Section 6.4</u> discusses the procedure to reset all DOTS telemetry setup configuration.

#### 6.2. Total Pipe Capacity

A DOTS client can communicate to its server(s) its DOTS client domain pipe information. The tree structure of the pipe information is shown in Figure 9.

Boucadair, et al. Expires November 9, 2020 [Page 20]

```
augment /ietf-signal:dots-signal/ietf-signal:message-type:
 +--:(telemetry-setup) {dots-telemetry}?
 +--rw telemetry* [cuid tsid]

        +--rw total-pipe-capacity* [link-id unit]
  |
              +--rw link-id nt:link-id
              +--rw capacity uint64
  +--rw unit
                              unit
         +--:(baseline)
          . . .
 +--:(telemetry) {dots-telemetry}?
    +--rw pre-or-ongoing-mitigation* [cuid tmid]
       . . .
```

```
Figure 9: Pipe Tree Structure
```

A DOTS client domain pipe is defined as a list of limits of (incoming) traffic volume (total-pipe-capacity") that can be forwarded over ingress interconnection links of a DOTS client domain. Each of these links is identified with a "link-id" [<u>RFC8345</u>].

The unit used by a DOTS client when conveying pipe information is captured in 'unit' attribute.

#### 6.2.1. Convey DOTS Client Domain Pipe Capacity

Similar considerations to those specified in <u>Section 6.1.2</u> are followed with one exception:

The relative order of two PUT requests carrying DOTS client domain pipe attributes from a DOTS client is determined by comparing their respective 'tsid' values. If such two requests have overlapping "link-id" and "unit", the PUT request with higher numeric 'tsid' value will override the request with a lower numeric 'tsid' value. The overlapped lower numeric 'tsid' MUST be automatically deleted and no longer be available.

DOTS clients SHOULD minimize the number of active 'tsids' used for pipe information. Typically, in order to avoid maintaining a long list of 'tsids' for pipe information, it is RECOMMENDED that DOTS

Boucadair, et al. Expires November 9, 2020 [Page 21]

clients include in any request to update information related to a given link the information of other links (already communicated using a lower 'tsid' value). Doing so, this update request will override these existing requests and hence optimize the number of 'tsid' request per DOTS client.

 Note: This assumes that all link information can fit in one single message.

For example, a DOTS client managing a single homed domain (Figure 10) can send a PUT request (shown in Figure 11) to communicate the capacity of "link1" used to connect to its ISP.

Figure 10: Single Homed DOTS Client Domain

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=457"
Content-Format: "application/dots+cbor"
{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "link1",
            "capacity": "500",
            "unit": "megabit-ps"
          }
        ]
      }
    ]
 }
}
   Figure 11: Example of a PUT Request to Convey Pipe Information
                           (Single Homed)
```

Boucadair, et al. Expires November 9, 2020 [Page 22]

DOTS Telemetry

DOTS clients may be instructed to signal a link aggregate instead of individual links. For example, a DOTS client managing a DOTS client domain having two interconnection links with an upstream ISP (Figure 12) can send a PUT request (shown in Figure 13) to communicate the aggregate link capacity with its ISP. Signalling individual or aggregate link capacity is deployment-specific.

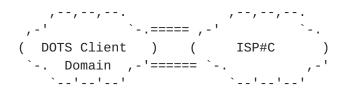

Figure 12: DOTS Client Domain with Two Interconnection Links

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=896"
Content-Format: "application/dots+cbor"
{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "aggregate",
            "capacity": "700",
            "unit": "megabit-ps"
          }
        1
      }
   1
 }
}
```

Figure 13: Example of a PUT Request to Convey Pipe Information (Aggregated Link)

Now consider that the DOTS client domain was upgraded to connect to an additional ISP (ISP#B of Figure 14), the DOTS client can inform a third-party DOTS server (that is, not hosted with ISP#A and ISP#B domains) about this update by sending the PUT request depicted in Figure 15. This request also includes information related to "link1" even if that link is not upgraded. Upon receipt of this request, the

Boucadair, et al. Expires November 9, 2020 [Page 23]

Internet-Draft

DOTS server removes the request with 'tsid=457' and updates its configuration base to maintain two links (link#1 and link#2).

   Figure 15: Example of a PUT Request to Convey Pipe Information
```

(Multi-Homed)

A DOTS client can delete a link by sending a PUT request with the 'capacity' attribute set to "0" if other links are still active for the same DOTS client domain (see <u>Section 6.2.3</u> for other delete cases). For example, if a DOTS client domain re-homes (that is, it changes its ISP), the DOTS client can inform its DOTS server about this update (e.g., from the network configuration in Figure 10 to the one shown in Figure 16) by sending the PUT request depicted in Figure 17. Upon receipt of this request, the DOTS server removes "link1" from its configuration bases for this DOTS client domain.

## 6.2.2. Retrieve Installed DOTS Client Domain Pipe Capacity

A GET request with 'tsid' Uri-Path parameter is used to retrieve a specific installed DOTS client domain pipe related information. The same procedure as defined in (Section 6.1.3) is followed.

To retrieve all pipe information bound to a DOTS client, the DOTS client proceeds as specified in <u>Section 6.1.1</u>.

#### 6.2.3. Delete Installed DOTS Client Domain Pipe Capacity

A DELETE request is used to delete the installed DOTS client domain pipe related information. The same procedure as defined in (Section 6.1.4) is followed.

#### 6.3. Telemetry Baseline

A DOTS client can communicate to its server(s) its normal traffic baseline and connections capacity:

Total traffic normal baseline: The percentile values representing the total traffic normal baseline. It can be represented for a target using 'total-traffic-normal'.

The traffic normal per protocol ('total-traffic-normal-perprotocol') baseline is represented for a target and is transportprotocol specific.

The traffic normal per port number ('total-traffic-normal-perport') baseline is represented for each port number bound to a target.

If the DOTS client negotiated percentile values and units (<u>Section 6.1</u>), these negotiated values will be used instead of the default ones.

- Total connections capacity: If the target is subjected to resource consuming DDoS attacks, the following optional attributes for the target per transport-protocol are useful to detect resource consuming DDoS attacks:
  - \* The maximum number of simultaneous connections that are allowed to the target.
  - \* The maximum number of simultaneous connections that are allowed to the target per client.

Boucadair, et al. Expires November 9, 2020 [Page 27]

- \* The maximum number of simultaneous embryonic connections that are allowed to the target. The term "embryonic connection" refers to a connection whose connection handshake is not finished. Embryonic connection is only possible in connectionoriented transport protocols like TCP or SCTP.
- \* The maximum number of simultaneous embryonic connections that are allowed to the target per client.
- \* The maximum number of connections allowed per second to the target.
- \* The maximum number of connections allowed per second to the target per client.
- \* The maximum number of requests allowed per second to the target.
- \* The maximum number of requests allowed per second to the target per client.
- \* The maximum number of partial requests allowed per second to the target. Attacks relying upon partial requests create a connection with a target but do not send a complete request (e.g., HTTP request).
- \* The maximum number of partial requests allowed per second to the target per client.

The aggregate per transport protocol is captured in 'totalconnection-capacity', while port-specific capabilities are represented using 'total-connection-capacity-per-port'.

The tree structure of the baseline is shown in Figure 18.

Figure 18: Telemetry Baseline Tree Structure

#### <u>6.3.1</u>. Convey DOTS Client Domain Baseline Information

Similar considerations to those specified in <u>Section 6.1.2</u> are followed with one exception:

The relative order of two PUT requests carrying DOTS client domain baseline attributes from a DOTS client is determined by comparing their respective 'tsid' values. If such two requests have overlapping targets, the PUT request with higher numeric 'tsid' value will override the request with a lower numeric 'tsid' value. The overlapped lower numeric 'tsid' MUST be automatically deleted and no longer be available.

Two PUT requests from a DOTS client have overlapping targets if there is a common IP address, IP prefix, FQDN, URI, or alias-name. Also, two PUT requests from a DOTS client have overlapping targets if the addresses associated with the FQDN, URI, or alias are overlapping with each other or with target-prefix.

DOTS clients SHOULD minimize the number of active 'tsids' used for baseline information. Typically, in order to avoid maintaining a long list of 'tsids' for baseline information, it is RECOMMENDED that DOTS clients include in a request to update information related to a given target, the information of other targets (already communicated using a lower 'tsid' value) (assuming this fits within one single datagram). This update request will override these existing requests and hence optimize the number of 'tsid' request per DOTS client.

If no target clause in included in the request, this is an indication that the baseline information applies for the DOTS client domain as a whole.

An example of a PUT request to convey the baseline information is shown in Figure 19.

        1
      }
    ]
  }
}
```

Figure 20: PUT to Convey the DOTS Traffic Baseline (2)

The traffic baseline information should be updated to reflect legitimate overloads (e.g., flash crowds) to prevent unnecessary mitigation.

Boucadair, et al. Expires November 9, 2020 [Page 32]

## 6.3.2. Retrieve Installed Normal Traffic Baseline

A GET request with 'tsid' Uri-Path parameter is used to retrieve a specific installed DOTS client domain baseline traffic information. The same procedure as defined in (<u>Section 6.1.3</u>) is followed.

To retrieve all baseline information bound to a DOTS client, the DOTS client proceeds as specified in <u>Section 6.1.1</u>.

## 6.3.3. Delete Installed Normal Traffic Baseline

A DELETE request is used to delete the installed DOTS client domain normal traffic baseline. The same procedure as defined in (Section 6.1.4) is followed.

#### 6.4. Reset Installed Telemetry Setup

Upon bootstrapping (or reboot or any other event that may alter the DOTS client setup), a DOTS client MAY send a DELETE request to set the telemetry parameters to default values. Such a request does not include any 'tsid'. An example of such request is depicted in Figure 21.

Header: DELETE (Code=0.04)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"

Figure 21: Delete Telemetry Configuration

## 6.5. Conflict with Other DOTS Clients of the Same Domain

A DOTS server may detect conflicts between requests to convey pipe and baseline information received from DOTS clients of the same DOTS client domain. 'conflict-information' is used to report the conflict to the DOTS client following similar conflict handling discussed in Section 4.4.1 of [I-D.ietf-dots-signal-channel]. The conflict cause can be set to one of these values:

1: Overlapping targets (already defined in [<u>I-D.ietf-dots-signal-channel</u>]).

TBA: Overlapping pipe scope (see <u>Section 11</u>).

Boucadair, et al. Expires November 9, 2020 [Page 33]

# 7. DOTS Pre-or-Ongoing Mitigation Telemetry

There are two broad types of DDoS attacks, one is bandwidth consuming attack, the other is target resource consuming attack. This section outlines the set of DOTS telemetry attributes (Section 7.1) that covers both the types of attacks. The objective of these attributes is to allow for the complete knowledge of attacks and the various particulars that can best characterize attacks.

The "ietf-dots-telemetry" YANG module (<u>Section 9.1</u>) augments the "ietf-dots-signal" with a new message type called "telemetry". The tree structure of the "telemetry" message type is shown Figure 24.

The pre-or-ongoing-mitigation telemetry attributes are indicated by the path-suffix '/tm'. The '/tm' is appended to the path-prefix to form the URI used with a CoAP request to signal the DOTS telemetry. Pre-or-ongoing-mitigation telemetry attributes specified in <u>Section 7.1</u> can be signaled between DOTS agents.

Pre-or-ongoing-mitigation telemetry attributes may be sent by a DOTS client or a DOTS server.

DOTS agents SHOULD bind pre-or-ongoing-mitigation telemetry data with mitigation requests relying upon the target clause. In particular, a telemetry PUT request sent after a mitigation request may include a reference to that mitigation request ('mid-list') as shown in Figure 22. An example illustrating requests correlation by means of 'target-prefix' is shown in Figure 23.

When generating telemetry data to send to a peer, the DOTS agent must auto-scale so that appropriate unit(s) are used.

Figure 22: Example of Request Correlation using 'mid'

Boucadair, et al. Expires November 9, 2020 [Page 34]

Figure 23: Example of Request Correlation using Target Prefix

DOTS agents MUST NOT send pre-or-ongoing-mitigation telemetry notifications to the same peer more frequently than once every 'telemetry-notify-interval' (Section 6.1). If a telemetry notification is sent using a block-like transfer mechanism (e.g., [I-D.bosh-core-new-block]), this rate limit policy MUST NOT consider these individual blocks as separate notifications, but as a single notification.

DOTS pre-or-ongoing-mitigation telemetry request and response messages MUST be marked as Non-Confirmable messages.

Boucadair, et al. Expires November 9, 2020 [Page 35]

```

Figure 25: Target Tree Structure

At least one of the attributes 'target-prefix', 'target-fqdn', 'target-uri', 'alias-name', or 'mid-list' MUST be present in the target definition.

If the target is subjected to bandwidth consuming attack, the attributes representing the percentile values of the 'attack-id' attack traffic are included.

If the target is subjected to resource consuming DDoS attacks, the same attributes defined for <u>Section 7.1.4</u> are applicable for representing the attack.

Boucadair, et al. Expires November 9, 2020 [Page 37]

This is an optional sub-attribute.

### 7.1.2. Total Traffic

The 'total-traffic' attribute (Figure 26) conveys the percentile values of total traffic observed during a DDoS attack. More granular total traffic can be conveyed in 'total-traffic-protocol' and 'total-traffic-port'.

The 'total-traffic-protocol' represents the total traffic for a target and is transport-protocol specific.

The 'total-traffic-port' represents the total traffic for a target per port number.

## 7.1.4. Total Attack Connections

If the target is subjected to resource consuming DDoS attack, the 'total-attack-connection' attribute is used to convey the percentile values of total attack connections. The following optional subattributes for the target per transport-protocol are included to represent the attack characteristics:

o The number of simultaneous attack connections to the target.

- o The number of simultaneous embryonic connections to the target.
- o The number of attack connections per second to the target.
- o The number of attack requests to the target.

The total attack connections per port number is represented using 'total-attack-connection-port' attribute.

#### 7.1.5. Attack Details

This attribute (Figure 29) is used to signal a set of details characterizing an attack. The following sub-attributes describing the on-going attack can be signal as attack details.

Boucadair, et al. Expires November 9, 2020 [Page 42]

vendor-id: Vendor ID is a security vendor's Enterprise Number as registered with IANA [Enterprise-Numbers]. It is a four-byte integer value.

attack-id: Unique identifier assigned for the attack.

- attack-name: Textual representation of the attack description. Natural Language Processing techniques (e.g., word embedding) can possibly be used to map the attack description to an attack type. Textual representation of attack solves two problems: (a) avoids the need to create mapping tables manually between vendors and (b) avoids the need to standardize attack types which keep evolving.
- attack-severity: Attack severity level. This attribute takes one of the values defined in <u>Section 3.12.2 of [RFC7970]</u>.
- start-time: The time the attack started. The attack's start time is
  expressed in seconds relative to 1970-01-01T00:00Z in UTC time
  (Section 2.4.1 of [RFC7049]). The CBOR encoding is modified so
  that the leading tag 1 (epoch-based date/time) MUST be omitted.
- end-time: The time the attack ended. The attack end time is
  expressed in seconds relative to 1970-01-01T00:00Z in UTC time
  (Section 2.4.1 of [RFC7049]). The CBOR encoding is modified so
  that the leading tag 1 (epoch-based date/time) MUST be omitted.
- source-count: A count of sources involved in the attack targeting the victim.
- top-talkers: A list of top talkers among attack sources. The top talkers are represented using the 'source-prefix'.

'spoofed-status' indicates whether a top talker is a spoofed IP address (e.g., reflection attacks) or not.

If the target is subjected to a bandwidth consuming attack, the attack traffic from each of the top talkers is included ('total-attack-traffic', <u>Section 7.1.3</u>).

If the target is subjected to a resource consuming DDoS attack, the same attributes defined in <u>Section 7.1.4</u> are applicable for representing the attack per talker.

Figure 29: Attack Detail Tree Structure

In order to optimize the size of telemetry data conveyed over the DOTS signal channel, DOTS agents MAY use the DOTS data channel [<u>I-D.ietf-dots-data-channel</u>] to exchange vendor-specific attack mapping details (that is, {vendor identifier, attack identifier} ==> attack name). As such, DOTS agents do not have to convey systematically an attack name in their telemetry messages over the

          Figure 30: Vendor Attack Mapping Tree Structure
```

A DOTS client sends a GET request to retrieve the capabilities supported by a DOTS server as per Section 7.1 of [<u>I-D.ietf-dots-data-channel</u>]. This request is meant to assess whether vendor attack mapping details feature is supported by the server (i.e., check the value of 'vendor-mapping-enabled').

If 'vendor-mapping-enabled' is set to 'true', A DOTS client MAY send a GET request to retrieve the DOTS server's vendor attack mapping details. An example of such GET request is shown in Figure 31.

GET /restconf/data/ietf-dots-data-channel:dots-data\
 /ietf-dots-mapping:vendor-mapping HTTP/1.1
Host: example.com
Accept: application/yang-data+json

Figure 31: GET to Retrieve the Vendor Attack Mappings of a DOTS Server

A DOTS client MAY retrieve only the list of vendors supported by the DOTS server. It does so by setting the "depth" parameter (<u>Section 4.8.2 of [RFC8040]</u>) to "3" in the GET request as shown in Figure 32. An example of a response body received from the DOTS server as a response to such request is illustrated in Figure 33.

Boucadair, et al. Expires November 9, 2020 [Page 45]

```
GET /restconf/data/ietf-dots-data-channel:dots-data\
    /ietf-dots-mapping:vendor-mapping?depth=3 HTTP/1.1
Host: example.com
Accept: application/yang-data+json
  Figure 32: GET to Retrieve the Vendors List used by a DOTS Server
{

    "ietf-dots-mapping:vendor": [
      {
        "ietf-dots-mapping:vendor-id": 1234,
        "ietf-dots-mapping:attack-mapping": []
      }
    ]
 }
}
Figure 33: Response to a GET to Retrieve the Vendors List used by a
                             DOTS Server
```

The DOTS client reiterates the above procedure regularly (e.g., once a week) to update the DOTS server's vendor attack mapping details.

If the DOTS client concludes that the DOTS server does not have any reference to the specific vendor attack mapping details, the DOTS client uses a POST request to install its vendor attack mapping details. An example of such POST request is depicted in Figure 34.

Boucadair, et al. Expires November 9, 2020 [Page 46]

```
POST /restconf/data/ietf-dots-data-channel:dots-data\
     /dots-client=dz6pHjaADkaFTbjr0JGBpw HTTP/1.1
Host: {host}:{port}
Content-Type: application/yang-data+json
{
  "ietf-dots-mapping:vendor-mapping": {
    "ietf-dots-mapping:vendor": [
      {
        "ietf-dots-mapping:vendor-id": 345,
        "ietf-dots-mapping:attack-mapping": [
          {
            "ietf-dots-mapping:attack-id": 1,
            "ietf-dots-mapping:attack-name":
               "Include a description of this attack"
          },
          {
            "ietf-dots-mapping:attack-id": 2,
            "ietf-dots-mapping:attack-name":
               "Again, include a description of the attack"
          }
        ]
     }
   ]
 }
}
```

Figure 34: POST to Install Vendor Attack Mapping Details

The DOTS server indicates the result of processing the POST request using the status-line. Concretely, "201 Created" status-line MUST be returned in the response if the DOTS server has accepted the vendor attack mapping details. If the request is missing a mandatory attribute or contains an invalid or unknown parameter, "400 Bad Request" status-line MUST be returned by the DOTS server in the response. The error-tag is set to "missing-attribute", "invalidvalue", or "unknown-element" as a function of the encountered error.

If the request is received via a server-domain DOTS gateway, but the DOTS server does not maintain a 'cdid' for this 'cuid' while a 'cdid' is expected to be supplied, the DOTS server MUST reply with "403 Forbidden" status-line and the error-tag "access-denied". Upon receipt of this message, the DOTS client MUST register (Section 5.1 of [I-D.ietf-dots-data-channel]).

The DOTS client uses the PUT request to modify its vendor attack mapping details maintained by the DOTS server (e.g., add a new mapping).

Boucadair, et al. Expires November 9, 2020 [Page 47]

#### DOTS Telemetry

A DOTS client uses a GET request to retrieve its vendor attack mapping details as maintained by the DOTS server (Figure 35).

```
GET /restconf/data/ietf-dots-data-channel:dots-data\
    /dots-client=dz6pHjaADkaFTbjr0JGBpw\
    /ietf-dots-mapping:vendor-mapping?\
    content=all HTTP/1.1
Host: example.com
Accept: application/yang-data+json
```

Figure 35: GET to Retrieve Installed Vendor Attack Mapping Details

When conveying attack details in DOTS telemetry messages (Sections 7.2, 7.3, and 8), DOTS agents MUST NOT include 'attack-name' attribute except if the corresponding attack mapping details were not shared with the peer DOTS agent (e.g., a DOTS server detects a new attack type).

### 7.2. From DOTS Clients to DOTS Servers

DOTS clients uses PUT request to signal pre-or-ongoing-mitigation telemetry to DOTS servers. An example of such request is shown in Figure 36.

Boucadair, et al. Expires November 9, 2020 [Page 48]

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tmid=123"
Content-Format: "application/dots+cbor"
{
  "ietf-dots-telemetry:telemetry": {
    "pre-or-ongoing-mitigation": [
      {
        "target": {
          "target-prefix": [
            "2001:db8::1/128"
          1
        },
        "total-attack-traffic-protocol": [
          {
            "protocol": 17,
            "unit": "megabit-ps",
            "mid-percentile-g": "900"
          }
        ],
        "attack-detail": [
          {
            "vendor-id": 1234,
            "attack-id": 77,
            "start-time": "1957811234",
            "attack-severity": "high"
          }
        ]
      }
    ]
 }
}
     Figure 36: PUT to Send Pre-or-Ongoing-Mitigation Telemetry
'cuid' is a mandatory Uri-Path parameter for PUT requests.
The following additional Uri-Path parameter is defined:
tmid: Telemetry Identifier is an identifier for the DOTS pre-or-
```

ongoing-mitigation telemetry data represented as an integer. This identifier MUST be generated by DOTS clients. 'tmid' values MUST increase monotonically (when a new PUT is generated by a DOTS client to convey pre-or-ongoing-mitigation telemetry).

Boucadair, et al. Expires November 9, 2020 [Page 49]

The procedure specified in Section 4.4.1 of [<u>I-D.ietf-dots-signal-channel</u>] MUST be followed for 'tmid' rollover.

This is a mandatory attribute.

'cuid' and 'tmid' MUST NOT appear in the PUT request message body.

At least 'target' attribute and another pre-or-ongoing-mitigation attributes (<u>Section 7.1</u>) MUST be present in the PUT request. If only the 'target' attribute is present, this request is handled as per <u>Section 7.3</u>.

The relative order of two PUT requests carrying DOTS pre-or-ongoingmitigation telemetry from a DOTS client is determined by comparing their respective 'tmid' values. If such two requests have overlapping 'target', the PUT request with higher numeric 'tmid' value will override the request with a lower numeric 'tmid' value. The overlapped lower numeric 'tmid' MUST be automatically deleted and no longer be available.

The DOTS server indicates the result of processing a PUT request using CoAP response codes. The response code 2.04 (Changed) is returned if the DOTS server has accepted the pre-or-ongoingmitigation telemetry. The error response code 5.03 (Service Unavailable) is returned if the DOTS server has erred. 5.03 uses Max-Age option to indicate the number of seconds after which to retry.

How long a DOTS server maintains a 'tmid' as active or logs the enclosed telemetry information is implementation-specific. Note that if a 'tmid' is still active, then logging details are updated by the DOTS server as a function of the updates received from the peer DOTS client.

A DOTS client that lost the state of its active 'tmids' or has to set 'tmid' back to zero (e.g., crash or restart) MUST send a GET request to the DOTS server to retrieve the list of active 'tmid'. The DOTS client may then delete 'tmids' that should not be active anymore (Figure 37). Sending a DELETE with no 'tmid' indicates that all 'tmids' must be deactivated (Figure 38).

Boucadair, et al. Expires November 9, 2020 [Page 50]

```

```

Figure 38: Delete All Pre-or-Ongoing-Mitigation Telemetry

#### 7.3. From DOTS Servers to DOTS Clients

The pre-or-ongoing-mitigation (attack details, in particular) can also be signaled from DOTS servers to DOTS clients. For example, the DOTS server co-located with a DDoS detector collects monitoring information from the target network, identifies DDoS attack using statistical analysis or deep learning techniques, and signals the attack details to the DOTS client.

The DOTS client can use the attack details to decide whether to trigger a DOTS mitigation request or not. Furthermore, the security operation personnel at the DOTS client domain can use the attack details to determine the protection strategy and select the appropriate DOTS server for mitigating the attack.

In order to receive pre-or-ongoing-mitigation telemetry notifications from a DOTS server, a DOTS client MUST send a PUT (followed by a GET) with the target filter. An example of such PUT request is shown in Figure 39. In order to avoid maintaining a long list of such requests, it is RECOMMENDED that DOTS clients include all targets in the same request. DOTS servers may be instructed to restrict the number of pre-or-ongoing-mitigation requests per DOTS client domain. This request MUST be maintained active by the DOTS server until a delete request is received from the same DOTS client to clear this pre-or-ongoing-mitigation telemetry.

The relative order of two PUT requests carrying DOTS pre-or-ongoingmitigation telemetry from a DOTS client is determined by comparing their respective 'tmid' values. If such two requests have overlapping 'target', the PUT request with higher numeric 'tmid' value will override the request with a lower numeric 'tmid' value.

Boucadair, et al. Expires November 9, 2020 [Page 51]

Header: GET (Code=0.01) Uri-Path: ".well-known" Uri-Path: "dots" Uri-Path: "tm" Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw" Observe: 0

Figure 41: GET to Subscribe to Telemetry Asynchronous Notifications for All 'tmids'

The DOTS client can filter out the asynchronous notifications from the DOTS server by indicating one or more Uri-Query options in its GET request. An Uri-Query option can include the following parameters: 'target-prefix', 'target-port', 'target-protocol', 'target-fqdn', 'target-uri', 'alias-name', 'mid', and 'c' (content) (Section 4.4). Furthermore:

If more than one Uri-Query option is included in a request, these options are interpreted in the same way as when multiple target clauses are included in a message body.

If multiple values of a query parameter are to be included in a request, these values MUST be included in the same Uri-Query option and separated by a "," character without any spaces.

Range values (i.e., contiguous inclusive block) can be included for 'target-port', 'target-protocol', and 'mid' parameters by indicating two bound values separated by a "-" character.

Wildcard names (i.e., a name with the leftmost label is the "\*" character) can be included in 'target-fqdn' or 'target-uri' parameters. DOTS clients MUST NOT include a name in which the "\*" character is included in a label other than the leftmost label. "\*.example.com" is an example of a valid wildcard name that can be included as a value of the 'target-fqdn' parameter in an Uri-Query option.

DOTS clients may also filter out the asynchronous notifications from the DOTS server by indicating a specific source information. To that aim, a DOTS client may include 'source-prefix', 'source-port', or 'source-icmp-type' in an Uri-Query option. The same considerations (ranges, multiple values) specified for target clauses apply for source clauses. Special care SHOULD be taken when using these filters as some attacks may be hidden to the requesting DOTS client (e.g., the attack changes its source information).

Boucadair, et al. Expires November 9, 2020 [Page 53]

DOTS Telemetry

Requests with invalid query types (e.g., not supported, malformed) by the DOTS server MUST be rejected by DOTS servers with a 4.00 (Bad Request).

An example of request to subscribe to asynchronous UDP telemetry notifications is shown in Figure 42. This filter will be applied for all 'tmids'.

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Query: "target-protocol=17"
Observe: 0
```

Figure 42: GET Request to Receive Telemetry Asynchronous Notifications Filtered using Uri-Query

The DOTS server will send asynchronous notifications to the DOTS client when an attack event is detected following similar considerations as in Section 4.4.2.1 of [<u>I-D.ietf-dots-signal-channel</u>]. An example of a pre-or-ongoingmitigation telemetry notification is shown in Figure 43.

  Figure 43: Message Body of a Pre-or-Ongoing-Mitigation Telemetry
```

Notification from the DOTS Server

A DOTS server sends the aggregate data for a target using 'totalattack-traffic' attribute. The aggregate assumes that Uri-Query filters are applied on the target. The DOTS server MAY include more granular data when needed (that is, 'total-attack-traffic-protocol' and 'total-attack-traffic-port'). If a port filter (or protocol filter) is included in a request, 'total-attack-traffic-protocol' (or 'total-attack-traffic-port') conveys the data with the port (or protocol) filter applied.

A DOTS server may aggregate pre-or-ongoing-mitigation data (e.g., 'top-talkers') for all targets of a domain, or when justified, send specific information (e.g., 'top-talkers') per individual targets.

Boucadair, et al. Expires November 9, 2020 [Page 55]

The DOTS client may log pre-or-ongoing-mitigation telemetry data with an alert sent to an administrator or a network controller. The DOTS client may send a mitigation request if the attack cannot be handled locally.

A DOTS client that is not interested to receive pre-or-ongoingmitigation telemetry data for a target MUST send a delete request similar to the one depicted in Figure 37.

#### 8. DOTS Telemetry Mitigation Status Update

8.1. DOTS Clients to Servers Mitigation Efficacy DOTS Telemetry Attributes

The mitigation efficacy telemetry attributes can be signaled from DOTS clients to DOTS servers as part of the periodic mitigation efficacy updates to the server (Section 5.3.4 of [<u>I-D.ietf-dots-signal-channel</u>]).

- Total Attack Traffic: The overall attack traffic as observed from the DOTS client perspective during an active mitigation. See Figure 27.
- Attack Details: The overall attack details as observed from the DOTS client perspective during an active mitigation. See <u>Section 7.1.5</u>.

The "ietf-dots-telemetry" YANG module augments the "mitigation-scope" type message defined in "ietf-dots-signal" so that these attributes can be signalled by a DOTS client in a mitigation efficacy update (Figure 44).

Boucadair, et al. Expires November 9, 2020 [Page 56]

```
augment /ietf-signal:dots-signal/ietf-signal:message-type
       /ietf-signal:mitigation-scope/ietf-signal:scope:
 +--rw total-attack-traffic* [unit] {dots-telemetry}?
 . . .
 +--rw attack-detail* [vendor-id attack-id] {dots-telemetry}?
    +--rw vendor-id
                             uint32
    +--rw attack-id
                             uint32
    +--rw attack-name?
                             string

    +--rw source-count
    | ...
    +--rw top-talker
       . . .
```

Figure 44: Telemetry Efficacy Update Tree Structure

In order to signal telemetry data in a mitigation efficacy update, it is RECOMMENDED that the DOTS client has already established a DOTS telemetry setup session with the server in 'idle' time.

Boucadair, et al. Expires November 9, 2020 [Page 57]

```

  }
}
```

Figure 45: An Example of Mitigation Efficacy Update with Telemetry Attributes

# <u>8.2</u>. DOTS Servers to Clients Mitigation Status DOTS Telemetry Attributes

The mitigation status telemetry attributes can be signaled from the DOTS server to the DOTS client as part of the periodic mitigation status update (Section 5.3.3 of [<u>I-D.ietf-dots-signal-channel</u>]). In particular, DOTS clients can receive asynchronous notifications of the attack details from DOTS servers using the Observe option defined in [<u>RFC7641</u>].

In order to make use of this feature, DOTS clients MUST establish a telemetry setup session with the DOTS server in 'idle' time and MUST set the 'server-originated-telemetry' attribute to 'true'.

Boucadair, et al. Expires November 9, 2020 [Page 58]

DOTS Telemetry

DOTS servers MUST NOT include telemetry attributes in mitigation status updates sent to DOTS clients for which 'server-originatedtelemetry' attribute is set to 'false'.

As defined in [RFC8612], the actual mitigation activities can include several countermeasure mechanisms. The DOTS server signals the current operational status to each relevant countermeasure. A list of attacks detected by each countermeasure MAY also be included. The same attributes defined for <u>Section 7.1.5</u> are applicable for describing the attacks detected and mitigated.

The "ietf-dots-telemetry" YANG module (<u>Section 9.1</u>) augments the "mitigation-scope" type message defined in "ietf-dots-signal" with telemetry data as depicted in following tree structure:

```
augment /ietf-signal:dots-signal/ietf-signal:message-type
       /ietf-signal:mitigation-scope/ietf-signal:scope:
 +--ro total-traffic* [unit] {dots-telemetry}?

        +--rw peak-c
           . . .
```

Figure 46 shows an example of an asynchronous notification of attack mitigation status from the DOTS server. This notification signals both the mid-percentile value of processed attack traffic and the peak percentile value of unique sources involved in the attack.

    ]
 }
}
  Figure 46: Response Body of a Mitigation Status With Telemetry
```

#### Attributes

DOTS clients can filter out the asynchronous notifications from the DOTS server by indicating one or more Uri-Query options in its GET request. A Uri-Query option can include the following parameters: 'target-prefix', 'target-port', 'target-protocol', 'target-fqdn', 'target-uri', 'alias-name', and 'c' (content) (Section 4.4). The considerations discussed in Section 7.3 MUST be followed to include multiple query values, ranges ('target-port', 'target-protocol'), and wildcard name ('target-fqdn', 'target-uri').

Boucadair, et al. Expires November 9, 2020 [Page 61]

An example of request to subscribe to asynchronous notifications bound to the "http1" alias is shown in Figure 47.

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "mitigate"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "mid=12332"
Uri-Query: "target-alias=https1"
Observe: 0
```

```
Figure 47: GET Request to Receive Asynchronous Notifications Filtered using Uri-Query
```

If the target query does not match the target of the enclosed 'mid' as maintained by the DOTS server, the latter MUST respond with a 4.04 (Not Found) error response code. The DOTS server MUST NOT add a new observe entry if this query overlaps with an existing one.

### 9. YANG Modules

## 9.1. DOTS Signal Channel Telemetry YANG Module

This module uses types defined in [RFC6991] and [RFC8345].

```
<CODE BEGINS> file "ietf-dots-telemetry@2020-05-04.yang"
module ietf-dots-telemetry {
  yang-version 1.1;
  namespace "urn:ietf:params:xml:ns:yang:ietf-dots-telemetry";

# **<u>11</u>**. IANA Considerationsr

# **<u>11.1</u>**. DOTS Signal Channel CBOR Key Values

This specification registers the DOTS telemetry attributes in the IANA "DOTS Signal Channel CBOR Key Values" registry available at <a href="https://www.iana.org/assignments/dots/dots.xhtml#dots-signal-channel-cbor-key-values">https://www.iana.org/assignments/dots/dots.xhtml#dots-signal-channel-cbor-key-values</a>.

The DOTS telemetry attributes defined in this specification are comprehension-optional parameters.

Note to the RFC Editor: (1) CBOR keys are assigned from the 32768-49151 range. (2) Please assign the following suggested values.

# **<u>11.2</u>**. DOTS Signal Channel Conflict Cause Codes

This specification requests IANA to assign a new code from the "DOTS Signal Channel Conflict Cause Codes" registry available at <u>https://www.iana.org/assignments/dots/dots.xhtml#dots-signal-channel-</u> <u>conflict-cause-codes</u>.

Code	Label	Description	Reference
TBA	overlapping-pipes	Overlapping pipe scope	[RFCXXXX]

# <u>11.3</u>. DOTS Signal Telemetry YANG Module

This document requests IANA to register the following URIs in the "ns" subregistry within the "IETF XML Registry" [<u>RFC3688</u>]:

Boucadair, et al. Expires November 9, 2020 [Page 100]

DOTS Telemetry

URI: urn:ietf:params:xml:ns:yang:ietf-dots-telemetry Registrant Contact: The IESG. XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-dots-mapping Registrant Contact: The IESG. XML: N/A; the requested URI is an XML namespace.

This document requests IANA to register the following YANG modules in the "YANG Module Names" subregistry [<u>RFC7950</u>] within the "YANG Parameters" registry.

name: ietf-dots-telemetry
namespace: urn:ietf:params:xml:ns:yang:ietf-dots-telemetry
maintained by IANA: N
prefix: dots-telemetry
reference: RFC XXXX
name: ietf-dots-mapping

namespace: urn:ietf:params:xml:ns:yang:ietf-dots-mapping
maintained by IANA: N
prefix: dots-mapping
reference: RFC XXXX

### **<u>12</u>**. Security Considerations

### **<u>12.1</u>**. DOTS Signal Channel Telemetry

Security considerations in Section 10 of [<u>I-D.ietf-dots-signal-channel</u>] need to be taken into consideration.

The DOTS telemetry information includes DOTS client network topology, DOTS client domain pipe capacity, normal traffic baseline and connections capacity, and threat and mitigation information. Such information is sensitive; it MUST be protected at rest by the DOTS server domain to prevent data leakage.

DOTS clients are typically trusted devices by the DOTS client domain. DOTS clients may be co-located on network security services (e.g., firewall) and a compromised security service potentially can do a lot more damage to the network. This assumption differs from the often held view that devices are untrusted, often referred to as the "zerotrust model". A compromised DOTS client can send fake DOTS telemetry data to a DOTS server to mislead the DOTS server. This attack can be prevented by monitoring and auditing DOTS clients to detect misbehavior and to deter misuse, and by only authorizing the DOTS client to convey the DOTS telemetry for specific target resources (e.g., an application server is authorized to exchange DOTS telemetry

Boucadair, et al. Expires November 9, 2020 [Page 101]

DOTS Telemetry

for its IP addresses but a DDoS mitigator can exchange DOTS telemetry for any target resource in the network). As a reminder, this is variation of dealing with compromised DOTS clients as discussed in Section 10 of [I-D.ietf-dots-signal-channel].

DOTS servers must be capable of defending themselves against DoS attacks from compromised DOTS clients. The following noncomprehensive list of mitigation techniques can be used by a DOTS server to handle misbehaving DOTS clients:

- o The probing rate (defined in Section 4.5 of
  [<u>I-D.ietf-dots-signal-channel</u>]) can be used to limit the average
  data rate to the DOTS server.
- o Rate-limiting DOTS telemetry, including those with new 'tmid' values, from the same DOTS client defends against DoS attacks that would result in varying the 'tmid' to exhaust DOTS server resources. Likewise, the DOTS server can enforce a quota and time-limit on the number of active pre-or-ongoing-mitigation telemetry data (identified by 'tmid') from the DOTS client.

Note also that telemetry notification interval may be used to ratelimit the pre-or-ongoing-mitigation telemetry notifications received by a DOTS client domain.

#### **<u>12.2</u>**. Vendor Attack Mapping

Security considerations in Section 10 of [<u>I-D.ietf-dots-data-channel</u>] need to be taken into consideration.

All data nodes defined in the YANG module specified in <u>Section 9.2</u> which can be created, modified, and deleted (i.e., config true, which is the default) are considered sensitive. Write operations to these data nodes without proper protection can have a negative effect on network operations. Appropriate security measures are recommended to prevent illegitimate users from invoking DOTS data channel primitives as discussed in [I-D.ietf-dots-data-channel]. Nevertheless, an attacker who can access a DOTS client is technically capable of undertaking various attacks, such as:

o Communicating invalid attack mapping details to the server ('/ietf-data:dots-data/ietf-data:dots-client/dotstelemetry:vendor-mapping'), which will mislead the server when correlating attack details.

Some of the readable data nodes in the YANG module specified in <u>Section 9.2</u> may be considered sensitive. It is thus important to

Boucadair, et al. Expires November 9, 2020 [Page 102]

control read access to these data nodes. These are the data nodes and their sensitivity:

- o '/ietf-data:dots-data/ietf-data:dots-client/dots-telemetry:vendormapping' can be misused to infer the DDoS protection technology deployed in a DOTS client domain.
- o '/ietf-data:dots-data/dots-telemetry:vendor-mapping' can be used by a compromised DOTS client to leak the attack detection capabilities of the DOTS server. This is a variation of the compromised DOTS client attacks discussed in Section 12.1.

#### **13**. Contributors
