DRIP Entity Tag Authentication Formats & Protocols for Broadcast Remote ID

Abstract

The Drone Remote Identification Protocol (DRIP), plus trust policies and periodic access to registries, augments Unmanned Aircraft System (UAS) Remote Identification (RID), enabling local real time assessment of trustworthiness of received RID messages and observed UAS, even by Observers then lacking Internet access. This document defines DRIP message types and formats to be sent in Broadcast RID Authentication Messages to verify that attached and recent detached messages were signed by the registered owner of the DRIP Entity Tag (DET) claimed.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 17 May 2024.

Table of Contents

1. Introduction

The initial regulations (e.g., [FAA-14CFR]) and standards (e.g., [F3411]) for Unmanned Aircraft (UA) Systems (UAS) Remote Identification and tracking (RID) do not address trust. However, this is a requirement that needs to be addressed for various different parties that have a stake in the safe operation of National Airspace Systems (NAS). DRIP's goal is to specify how RID can be made trustworthy and available in both Internet and local-only connected scenarios, especially in emergency situations.

UAS often operate in a volatile environment. Small UA offer little capacity for computation and communication. UAS RID must also be accessible with ubiquitous and inexpensive devices without modification. This limits options.

Generally, two communication schemes for UAS RID are considered: Broadcast and Network. This document focuses on adding trust to Broadcast RID (Section 3.2 of [RFC9153]).

Senders can make any claims the RID message formats allow. Observers have no standardized means to assess the trustworthiness of message content, nor verify whether the messages were sent by the UA identified therein, nor confirm that the UA identified therein is the one they are visually observing. Indeed, Observers have no way to detect whether the messages were sent by a UA, or spoofed by some other transmitter (e.g., a laptop or smartphone) anywhere in direct wireless broadcast range.

1.1. DET Authentication Goals for Broadcast RID

ASTM [F3411] Authentication Messages (Message Type 0x2), when used with DET-based formats, enable a high level of trust that the content of other ASTM Messages was generated by their claimed registered source. These messages are designed to provide the Observers with immediately actionable information.

This authentication approach also provides some error correction (Section 5) as mandated by the United States (US) Federal Aviation Administration (FAA) [FAA-14CFR], which is missing from [F3411] over Legacy Transports (Bluetooth 4.x).

These DRIP enhancements to [F3411] further support the important use case of Observers who may be offline at the time of observation.

A summary of DRIP requirements [RFC9153] addressed herein is provided in Section 7.

> Note: The Endorsement (used in Section 4.2) that proves that a DET is registered MUST come from its immediate parent in the registration hierarchy, e.g., a DRIP Identity Management Entity (DIME) [drip-registries]. In the definitive hierarchy, the parent of the UA is its HDA, the parent of an HDA is its RAA, etc. It is also assumed that all DRIP-aware entities use a DET as their identifier during interactions with other DRIP-aware entities.

2. Terminology

2.1. Required Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2.2. Definitions

This document makes use of the terms (Observer, USS, UTM, etc.) defined in [RFC9153]. Other terms (such as DIME) are from [RFC9434], while others (DET, RAA, HDA, etc.) are from [RFC9374].

In addition, the following terms are defined for this document:

ASTM Message (25 bytes):

: Full ASTM Message as defined in [F3411]; specifically Message Types 0x0, 0x1, 0x3, 0x4, and 0x5

ASTM Message Hash (8 bytes):

: Hash of a single full ASTM Message using hash operations described in (Section 4.4.3). ASTM Message includes Message Type and Protocol Version and does not include the Message Counter.

Broadcast Endorsement (136 bytes):

: A class of Endorsement under DRIP which is carried by the Link Message Section 4.2. They are generated by a DIME during the registration of a subordinate DET-based entity.

Current Manifest Hash (8 bytes):

: Hash of the current Manifest Message (Section 4.4). See Section 4.4.2.

Evidence (0 to 112 bytes):

: Opaque evidence data that the UA is endorsing during its flight in Figure 4.

Extended Transports:

: Use of extended advertisements (Bluetooth 5.x), service info (Wi-Fi NAN) or vendor specific element information (IEEE 802.11 Beacon) in broadcast frames as specified in [F3411]. Must use ASTM Message Pack (Message Type 0xF).

Frame Type (1 byte):

: Sub-type for future different DRIP Frame formats. See Section 4.5.1.

Legacy Transports:

: Use of broadcast frames (Bluetooth 4.x) as specified in [F3411].

Previous Manifest Hash (8 bytes):

Hash of the previously sent Manifest Message (Section 4.4). See Section 4.4.2.

UA DRIP Entity Tag (DET) (16 bytes):

The UA DET [RFC9374] in byte form (network byte order) and is part of Figure 4.

UA Signature (64 bytes):

Signature over all 4 preceding fields of Figure 4 using the Host Identity (HI) of the UA.

Valid Not After (VNA) Timestamp by UA (4 bytes):

Timestamp denoting recommended time to stop trusting data in Figure 4. MUST follow the format defined in [F3411]. That is a Unix-style timestamp (with an epoch of 2019-01-01 00:00:00 UTC) with an additional offset to push a short time into the future (relative to Not Before Timestamp) to avoid replay attacks. The offset used against the Unix-style timestamp is not defined in this document. Best practice identifying an acceptable offset should be used taking into consideration the UA environment, and propagation characteristics of the messages being sent, and clock differences between the UA and Observers. A reasonable time would be to set Not After Timestamp 2 minutes after Not Before Timestamp.

Valid Not Before (VNB) Timestamp by UA (4 bytes):

Timestamp denoting recommended time to start trusting data in Figure 4. MUST follow the format defined in [F3411]. That is, a Unix-style timestamp with an epoch of 2019-01-01 00:00:00 UTC. MUST be set no earlier than the time the signature is generated.

3. Background

3.1. Reasoning for IETF DRIP Authentication

[F3411] defines Authentication Message framing only. It does not define authentication formats or methods. It explicitly anticipates several signature options but does not fully define those. Annex A1 of [F3411] defines a Broadcast Authentication Verifier Service, which has a heavy reliance on Observer real-time connectivity to the Internet. Fortunately, [F3411] also allows third party standard Authentication Types using Type 5 Specific Authentication Method (SAM), several of which DRIP defines herein.

The standardization of specific formats to support the DRIP requirements in UAS RID for trustworthy communications over Broadcast RID is an important part of the chain of trust for a UAS ID. Per Section 5 of [RFC9434], Authentication formats are needed to relay information for Observers to determine trust. No existing formats (defined in [F3411] or other organizations leveraging this feature) provide the functionality to satisfy this goal resulting in the work reflected in this document.

3.1.1. UA Signed Evidence

When an Observer receives a DRIP-based Authentication Message (Section 4.3, Section 4.4, or Section 4.5) containing UA-signed Evidence (in an Endorsement structure Section 4.1) it MUST validate the signature using the HI corresponding to the UA's DRIP Entity Tag (DET).

The UA's HI SHOULD be retrieved from DNS. If not available it may have been revoked. Note that accurate revocation status is a DIME inquiry; DNS non-response is a hint that a DET is expired or revoked. It MAY be retrieved from a local cache, if present. The local cache is typically populated by DNS lookups and/or by received Broadcast Endorsements (Section 3.1.2).

Once the Observer has the registered UA's DET and HI, all further (or cached previous) DRIP-based Authentication Messages using the UA DET can be validated. Signed content, tied to the DET, can now be trusted to have been signed by the holder of the private key corresponding to the DET.

Whether the content is true is a separate question which DRIP cannot address, but sanity checks (Section 6) are possible.

3.1.2. DIME Endorsements of Subordinate DET

When an Observer receives a DRIP Link Authentication Message (Section 4.2) containing an Endorsement by the DIME of a child DET registration, it MUST validate the signature using the HI corresponding to the DIME's DET.

The DIME's HI, SHOULD be retrieved from DNS (e.g., Section 5 of [drip-registries]), when available. It MAY be cached from a prior DNS lookup or be stored in a distinct local store.

3.1.3. DIME Hierarchy Endorsements

An Observer can receive a series of DRIP Link Authentication Messages (Section 4.2), each one pertaining to a DIME's registration in the DIME above it in the hierarchy. Similar to Section 3.1.2, each link in this chain MUST be validated.

3.1.4. UAS RID Trust

Section 3.1.1, Section 3.1.2, and Section 3.1.3 complete the trust chain for the claimed DET and associated HI (public key), but the chain cannot yet be trusted as having any relevance to the observed UA because replay attacks are trivial. At this point, the key nominally possessed by the UA is trusted but the UA has not yet been proven to possess that private key.

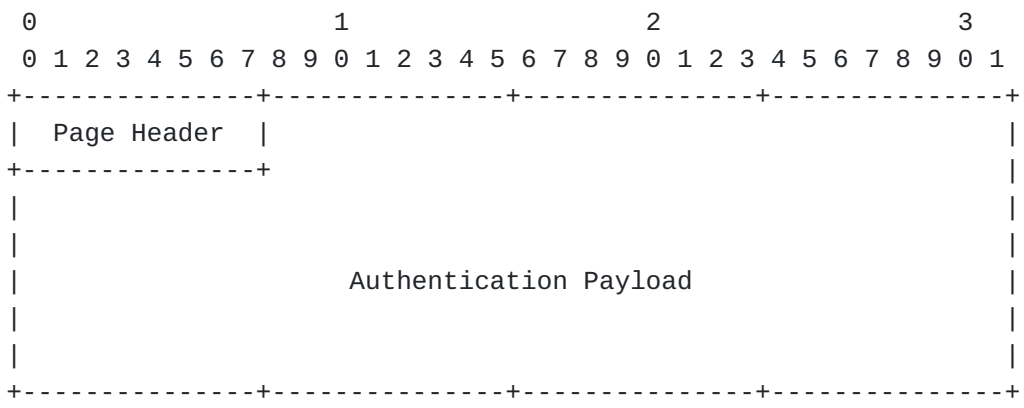
It is necessary for the UA to prove possession by dynamically signing data that is unique and unpredictable but easily verified by the Observer. This can be a DRIP Wrapper or Manifest (Section 4.3, Section 4.4) containing an ASTM Message that fulfills the requirements. Verification of this signed data MUST be performed by the Observer as part of the received UAS RID information trust assessment (Section 6.4.2).

3.2. ASTM Authentication Message

The Authentication Message (Message Type 0x2) is unique in the [F3411] Broadcast standard as it is the only message that can be larger than the Legacy Transport size. To address this, it is defined as a set of "pages", each of which fits into a single Legacy Transport frame. For Extended Transports these pages are still used but are all in a single frame.

3.2.1. Authentication Page

This document leverages Authentication Type 0x5, Specific Authentication Method (SAM), as the principal authentication container, defining a set of SAM Types in Section 4. Authentication Type is encoded in every Authentication Page in the Page Header. The SAM Type is defined as a field in the Authentication Payload (see Section 3.2.3.1).



Page Header: (1 byte)
    Authentication Type (4 bits)
    Page Number (4 bits)

Authentication Payload: (23 bytes per page)
    Authentication Payload, including headers. Null padded.

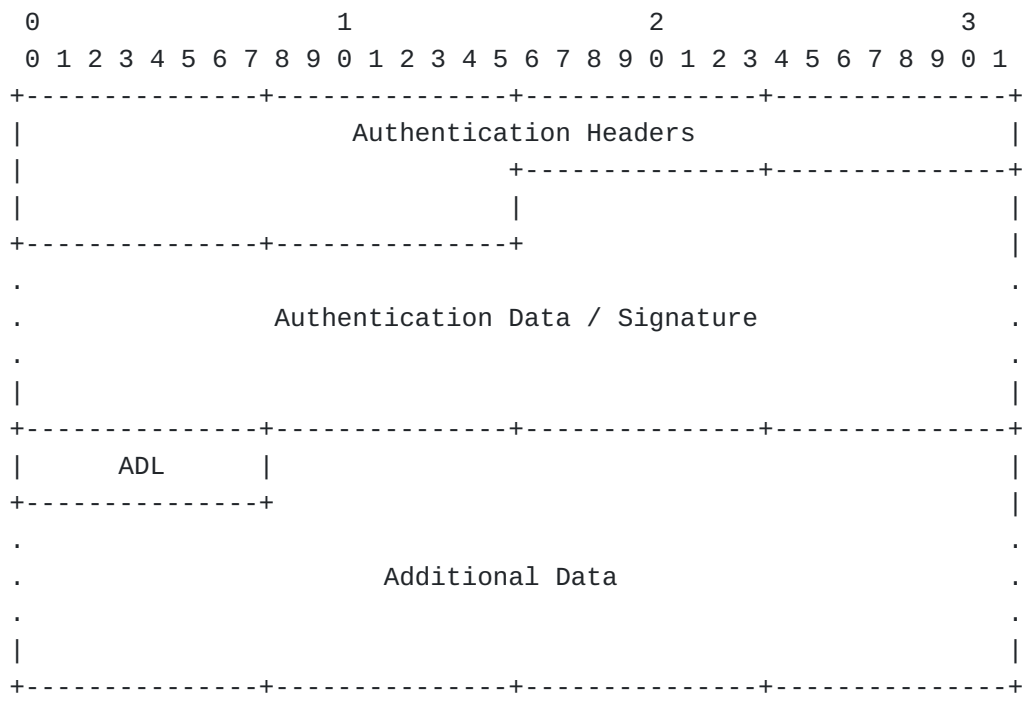
Figure 1: Standard ASTM Authentication Message Page

The Authentication Message is structured as a set of pages per Figure 1. There is a technical maximum of 16 pages (indexed 0 to 15 in the Page Header) that can be sent for a single Authentication Message, with each page carrying a maximum 23-byte Authentication Payload. See Section 3.2.4 for more details. Over Legacy Transports, these messages are "fragmented", with each page sent in a separate Legacy Transport frame.

Either as a single Authentication Message or a set of fragmented Authentication Message Pages, the structure is further wrapped by outer ASTM framing and the specific link framing.

3.2.2. Authentication Payload Field

Figure 2 is the source data view of the data fields found in the Authentication Message as defined by [F3411]. This data is placed into Figure 1's Authentication Payload, spanning multiple pages.



Authentication Headers: (6 bytes)
    As defined in F3411.

Authentication Data / Signature: (255 bytes at maximum)
    Opaque authentication data.

Additional Data Length (ADL): (1 byte - unsigned)
    Length in bytes of Additional Data.

Additional Data: (255 bytes max):
    Data that follows the Authentication Data / Signature but
    is not considered part of the Authentication Data.

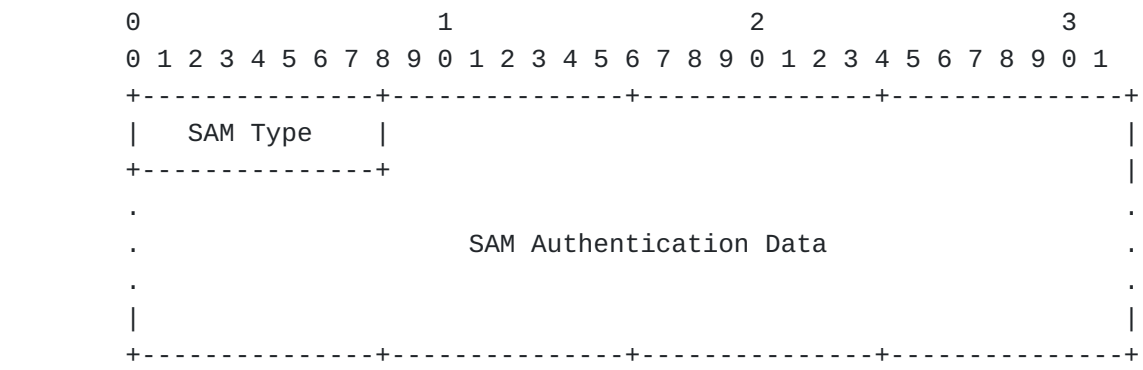
Figure 2: ASTM Authentication Message Fields

When Additional Data is being sent, a single unsigned byte (Additional Data Length) directly follows the Authentication Data / Signature and has the length, in bytes, of the following Additional Data. For DRIP, this field is used to carry Forward Error Correction as defined in Section 5.

3.2.3. Specific Authentication Method

3.2.3.1. SAM Data Format

Figure 3 is the general format to hold authentication data when using SAM and is placed inside the Authentication Data/Signature field in Figure 2.



SAM Type (1 byte):
Byte defined by F3411 to multiplex SAMs

SAM Authentication Data (0 to 200 bytes):
Authentication data (opaque to baseline F3411 but parsed by DRIP).

Figure 3: SAM Data Format

3.2.3.1.1. SAM Type

The following SAM Types are allocated to DRIP:

SAM Type	Description
0x01	DRIP Link (Section 4.2)
0x02	DRIP Wrapper (Section 4.3)
0x03	DRIP Manifest (Section 4.4)
0x04	DRIP Frame (Section 4.5)

Table 1: DRIP SAM Types

> Note: ASTM International is the owner of these code points as they are defined in [F3411]. In accordance with [F3411] Annex 5, the International Civil Aviation Organization (ICAO) has been selected by ASTM as the registrar to manage allocations of these code points.

3.2.3.1.2. SAM Authentication Data

This field has a maximum size of 200 bytes, as defined by Section 3.2.4.

3.2.4. ASTM Broadcast RID Constraints

3.2.4.1. Wireless Frame Constraints

A UA has the option of broadcasting using Bluetooth (4.x and 5.x), Wi-Fi NAN, or IEEE 802.11 Beacon, see Section 6. With Bluetooth, FAA and other Civil Aviation Authorities (CAA) mandate transmitting simultaneously over both 4.x and 5.x. The same application layer

information defined in [F3411] MUST be transmitted over all the physical layer interfaces performing the function of RID.

Bluetooth 4.x presents a payload size challenge in that it can only transmit 25 bytes of payload per frame while the others can all support larger payloads per frame. However, the [F3411] messaging framing dictated by Bluetooth 4.x constraints is inherited by [F3411] over other media.

3.2.4.2. Paged Authentication Message Constraints

To keep consistent formatting across the different transports (Legacy and Extended) and their independent restrictions, the authentication data being sent is REQUIRED to fit within the page limit that the most constrained existing transport can support. Under Broadcast RID, the Extended Transport that can hold the least amount of authentication data is Bluetooth 5.x at 9 pages.

As such DRIP transmitters are REQUIRED to adhere to the following when using the Authentication Message:

1. Authentication Data / Signature data MUST fit in the first 9 pages (Page Numbers 0 through 8).

2. The Length field in the Authentication Headers (which encodes the length in bytes of Authentication Data / Signature only) MUST NOT exceed the value of 201. This includes the SAM Type but excludes Additional Data such as FEC.

4. DRIP Authentication Formats

All formats defined in this section are the content of the Authentication Data/Signature field in Figure 2 and use the Specific Authentication Method (SAM, Authentication Type 0x5). The first byte of the Authentication Data / Signature of Figure 2 is used to multiplex among these various formats.

When sending data over a medium that does not have underlying Forward Error Correction (FEC), for example Legacy Transports, then Section 5 MUST be used.

Appendix A provides a high-level overview of the various states of trustworthiness.

4.1. Endorsement Structure for UA Signed Evidence

The Endorsement Structure for UA Signed Evidence (Figure 4) is used by the UA during flight to sign over information elements using the private key associated with the current UA DET. It is encapsulated by the SAM Authentication Data field of Figure 3.

This structure is used by the DRIP Wrapper (Section 4.3), Manifest Section 4.4, and Frame (Section 4.5). DRIP Link (Section 4.2) MUST NOT use it as it will not fit in the ASTM Authentication Message with its intended content (i.e., a Broadcast Endorsement).

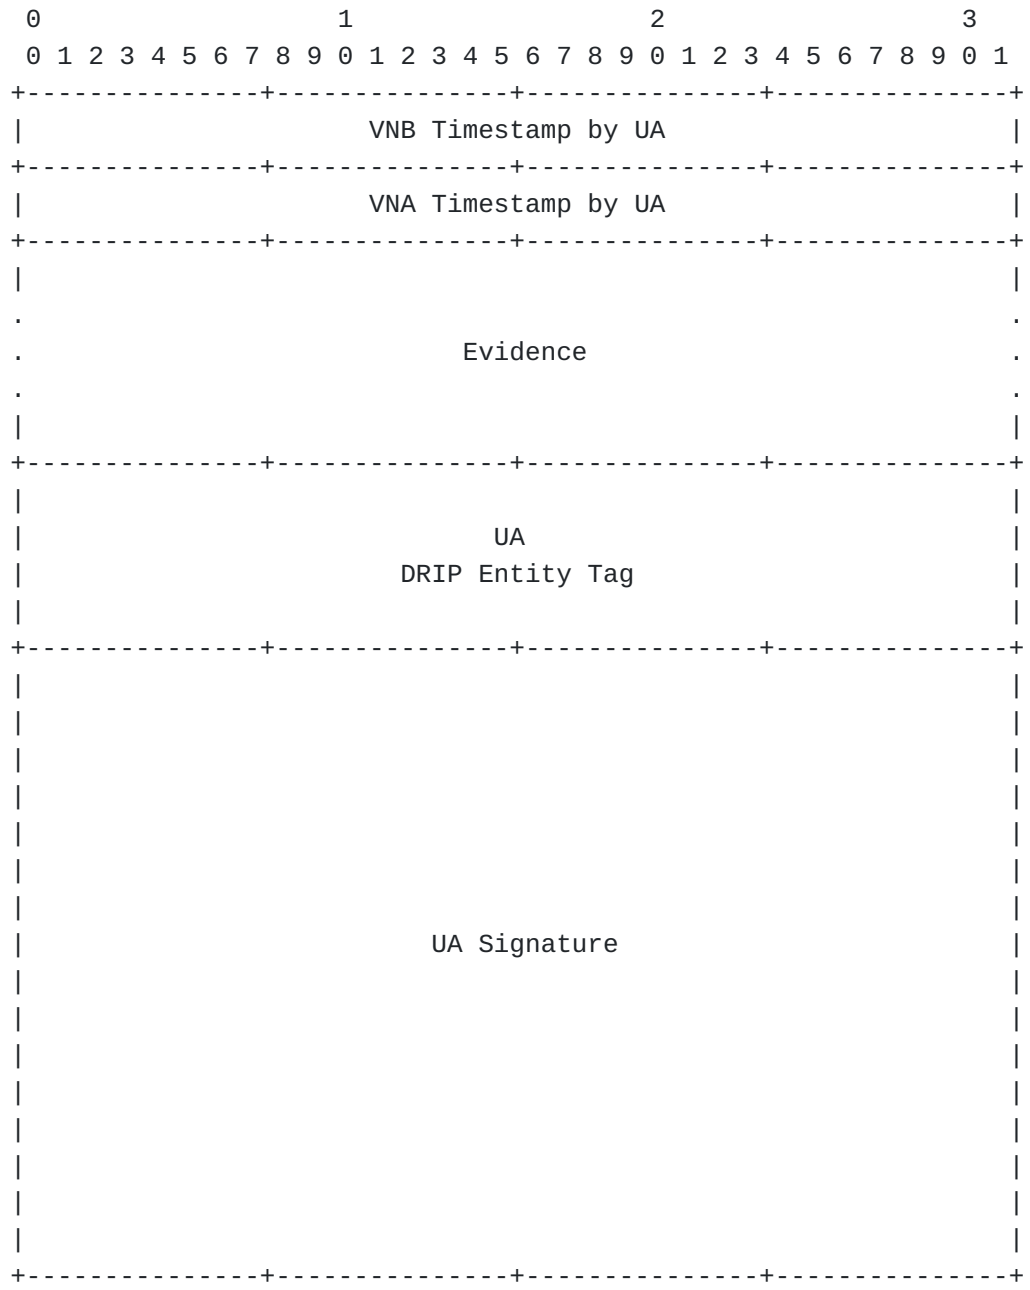


Figure 4: Endorsement Structure for UA Signed Evidence

UA DRIP Entity Tag:

This is the current DET [RFC9374] being used by the UA.

Evidence:

The evidence section MUST be filled in with data in the form of an opaque object specified in the DRIP Wrapper, Manifest, or Frame sections.

UA Signature:

The UA private key MUST be used over all preceding fields to generate the signature.

When using this structure, the UA is minimally self-endorsing its DET. The HI of the UA DET can be looked up by mechanisms described in [drip-registries] or by extracting it from a Broadcast Endorsement (see Section 4.2 and Section 6.3).

4.2. DRIP Link

This SAM Type is used to transmit Broadcast Endorsements. For example, the Broadcast Endorsement: HDA, UA is sent (see Section 6.3) as a DRIP Link message.

DRIP Link is important as its contents are used to provide trust in the DET/HI pair that the UA is currently broadcasting. This message does not require Internet connectivity to perform signature validations of the contents when the DIME DET/HI is in the receiver's cache. It also provides the UA HI, when it is a Broadcast Endorsement: HDA, UA, so that connectivity is not required when performing validation of other DRIP Authentication Messages.

VNB Timestamp by Parent (4 bytes):
    Current time at signing, set by Parent Entity.

VNA Timestamp by Parent (4 bytes):
    Timestamp denoting recommended time to trust Endorsement.

DET of Child: (16 bytes)
    DRIP Entity Tag of Child Entity.

HI of Child: (32 bytes)
    Host Identity of Child Entity.

DET of Parent: (16 bytes)
    DRIP Entity Tag of Parent Entity.

Signature by Parent(64 bytes):
    Signature over preceding fields using the keypair of
    the Parent DET.

Figure 5: Broadcast Endorsement / DRIP Link

This DRIP Authentication Message is used in conjunction with other DRIP SAM Types (such as the Manifest or the Wrapper) that contain data (e.g., the ASTM Location/Vector Message, Message Type 0x2) that is guaranteed to be unique, unpredictable, and easily cross-checked by the receiving device.

A hash of the final link (Broadcast Endorsement: HDA on UA) in the Broadcast Endorsement chain SHOULD be included in each DRIP Manifest Section 4.4.

4.3. DRIP Wrapper

This SAM Type is used to wrap and sign over a list of other [F3411] Broadcast RID messages.

The evidence section of the Endorsement Structure for UA Signed Evidence (Section 4.1) is populated with full (25-byte) [F3411] Broadcast RID messages. The ASTM Messages can be concatenated together to form a contiguous byte sequence, as shown in Figure 6.

The maximum number of messages supported is 4. The messages MUST be in Message Type order as defined by [F3411]. All message types except Authentication (Message Type 0x2) and Message Pack (Message Type 0xF) are allowed.

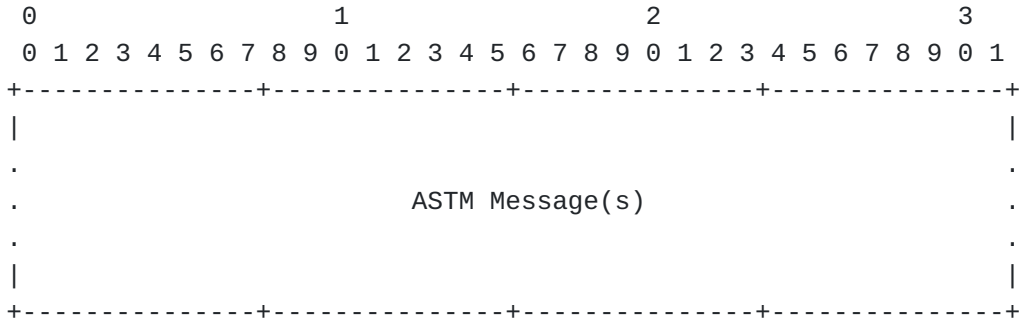

Figure 6: DRIP Wrapper Evidence

4.3.1. Wrapped Count & Sanity Check

When decoding a DRIP Wrapper on a receiver, a calculation of the number of messages wrapped and a sanity check can be performed by using the number of bytes (defined as wrapperLength) between the UA DET and the VNB Timestamp by UA as shown in Figure 7.

```
if (wrapperLength MOD 25) != 0 {
  return DECODE_FAILURE
}
wrappedCount = wrapperLength / 25;
```

Figure 7: Pseudo-code for Wrapper sanity check and number of messages calculation

4.3.2. Wrapper over Extended Transports

To send the DRIP Wrapper over Extended Transports, the messages being wrapped are co-located with the Authentication Message in an ASTM Message Pack (Message Type 0xF). The evidence section of the Endorsement Structure for UA Signed Evidence is cleared after signing, leaving the following binary structure that is placed into the SAM Authentication Data of Figure 3 and sent in the same Message Pack.

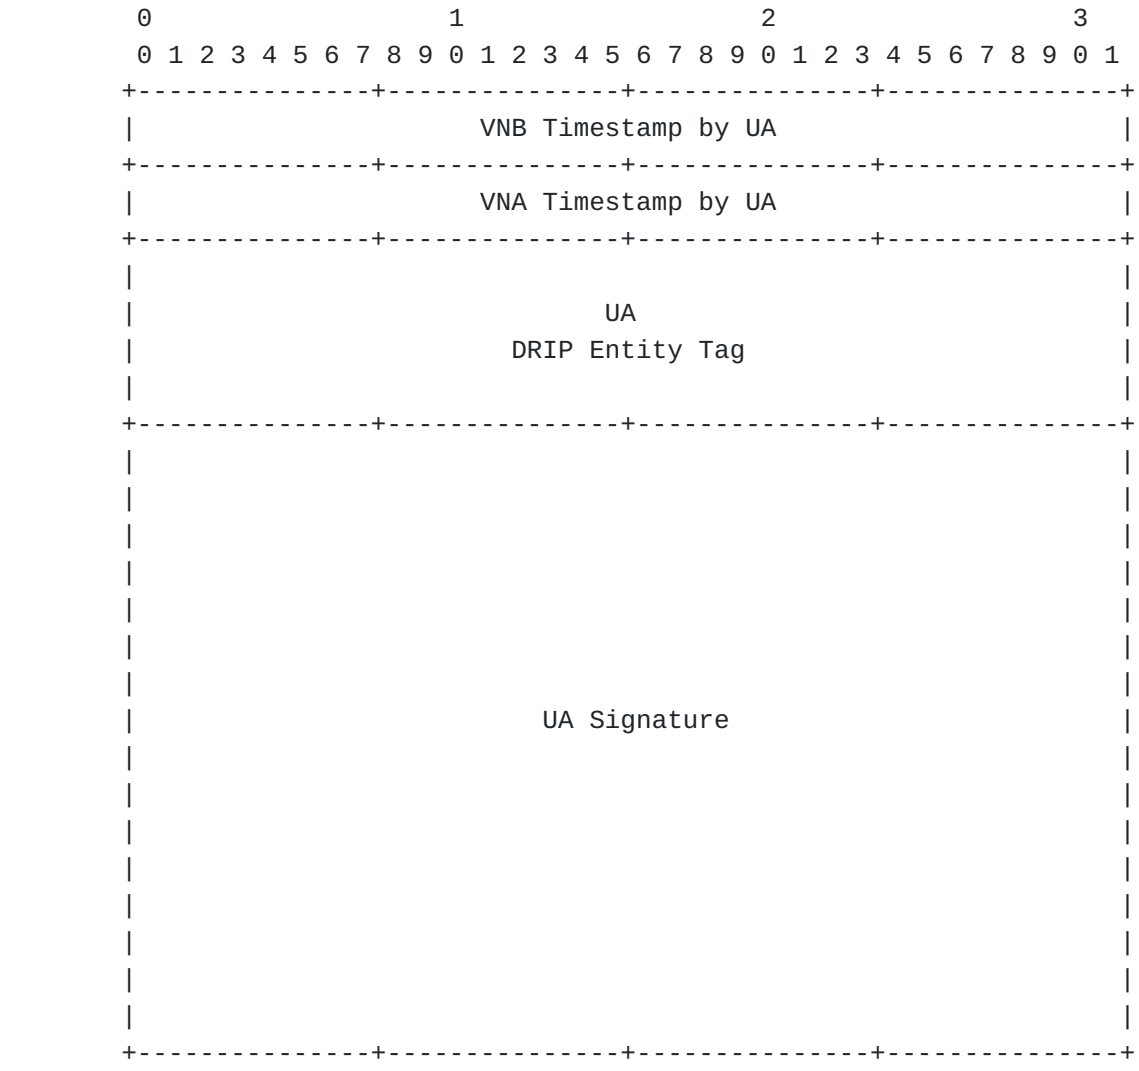

Figure 8: DRIP Wrapper over Extended Transports

To verify the signature, the receiver must concatenate all the messages in the Message Pack (excluding Authentication Message found in the same Message Pack) in Message Type order and set the evidence section of the Endorsement Structure for UA Signed Evidence before performing signature verification.

The functionality of a Wrapper in this form is equivalent to Message Set Signature (Authentication Type 0x3) when running over Extended Transports. What the Wrapper provides is the same format but over both Extended and Legacy Transports allowing the transports to be similar. Message Set Signature also implies using the ASTM validator system architecture which depends on Internet connectivity for verification which the receiver may not have at the time of receipt of an Authentication Message. This is something the Wrapper, and all DRIP Authentication Formats, avoid when the UA key is obtained via a DRIP Link Authentication Message.

4.3.3. Wrapper Limitations

The primary limitation of the Wrapper is the bounding of up to 4 ASTM Messages that can be sent within it. Another limitation is that the format cannot be used as a surrogate for messages it is wrapping due to the high potential that a receiver on the ground does not support DRIP. Thus, when a Wrapper is being used, the wrapped data must effectively be sent twice, once as a single framed message (as specified in [F3411]) and then again within the Wrapper.

4.4. DRIP Manifest

This SAM Type is used to create message manifests that contain hashes of previously sent ASTM Messages.

By hashing previously sent messages and signing them, we gain trust in a UA's previous reports without re-transmitting them. This is a way to evade the limitation of a maximum of 4 messages in the Wrapper (Section 4.3.3) and greatly reduce overhead.

An Observer who has been listening for any length of time MUST hash received messages and cross-check them against the Manifest hashes.

Judicious use of a Manifest enables an entire Broadcast RID message stream to be strongly authenticated with less than 100% overhead relative to a completely unauthenticated message stream (see Appendix B).

The evidence section of the Endorsement Structure for UA Signed Evidence (Section 4.1) is populated with 8-byte hashes of [F3411] Broadcast RID messages (from 2 to 11) and two special hashes

(Section 4.4.2). All these hashes MUST be concatenated to form a contiguous byte sequence in the evidence section. The Previous Manifest Hash and Current Manifest Hash MUST always come before the ASTM Message Hashes as seen in Figure 9.

A receiver SHOULD use the Manifest to verify each ASTM Message hashed therein that it has previously received. It can do this without having received them all. A Manifest SHOULD typically encompass a single transmission cycle of messages being sent, see Section 6.4 and Appendix B.

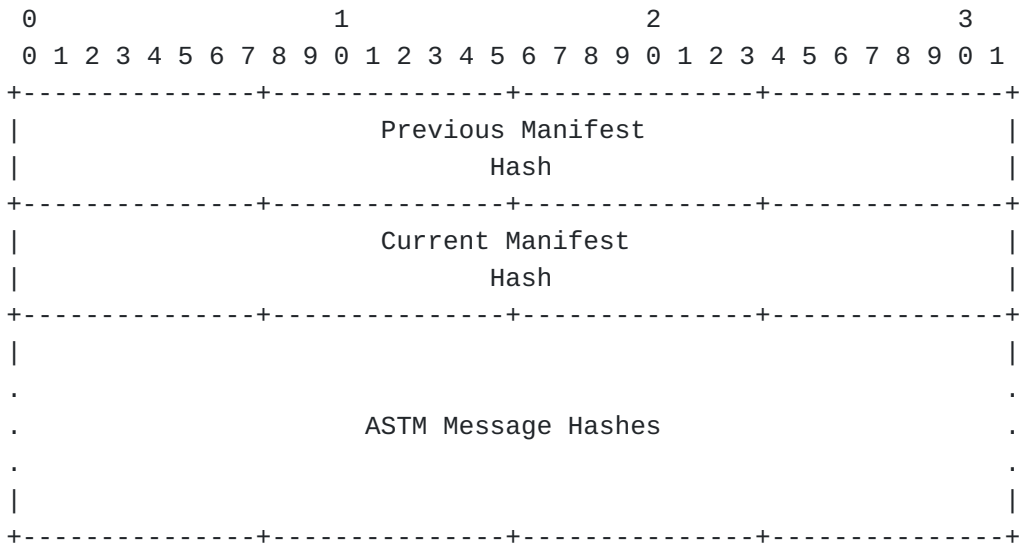

Figure 9: DRIP Manifest Evidence Structure

4.4.1. Hash Count & Sanity Check

When decoding a DRIP Manifest on a receiver, a calculation of the number of hashes and a sanity check can be performed by using the number of bytes (defined as manifestLength) between the UA DET and the VNB Timestamp by UA such as shown in Figure 10.

```
hashLength = 8
if (manifestLength MOD hashLength) != 0 {
  return DECODE_FAILURE
}
hashCount = (manifestLength / hashLength) - 2;
```

Figure 10: Pseudo-code for Manifest Sanity Check and Number of Hashes Calculation

4.4.2. Manifest Ledger Hashes

Two special hashes are included in all Manifests: the Previous Manifest Hash, which links to the previous Manifest, and the Current Manifest Hash. These hashes act as a ledger of provenance to the Manifest that could be traced back if the Observer was present for extended periods of time.

4.4.3. Hash Algorithms and Operation

The hash algorithm used for the Manifest is the same hash algorithm used in creation of the DET [RFC9374] that is signing the Manifest.

DET's using cSHAKE128 [NIST.SP.800-185] compute the hash as follows:

```
cSHAKE128(ASTM Message, 64, "", "Remote ID Auth Hash")
```

> Informative Note: for OGAs other than "5" [RFC9374], use the construct appropriate for the associated hash. e.g. for "2" which is ECDSA/SHA-384: Ltrunc(SHA-384(ASTM Message | "Remote ID Auth Hash"), 8)

When building the list of hashes, the Previous Manifest Hash is known from the previous Manifest. For the first built Manifest this value is filled with a random nonce. The Current Manifest Hash is null filled while ASTM Messages are hashed and fill the ASTM Messages Hashes section. When all messages are hashed, the Current Manifest Hash is computed over the Previous Manifest Hash, Current Manifest Hash (null filled) and ASTM Messages Hashes. This hash value replaces the null filled Current Manifest Hash and becomes the Previous Manifest Hash for the next Manifest.

4.4.3.1. Legacy Transport Hashing

Under this transport DRIP hashes the full ASTM Message being sent over the Bluetooth Advertising frame. For paged ASTM Messages (currently only Authentication Messages) all the pages are concatenated together and hashed as one object. For all other Message Types each individual 25-byte message is hashed.

4.4.3.2. Extended Transport Hashing

Under this transport DRIP hashes the full ASTM Message Pack (Message Type 0xF) - regardless of its content.

4.5. DRIP Frame

This SAM Type is used when the authentication data does not fit in other defined formats under DRIP and is reserved for future expansion under DRIP if required.

The contents of Frame Evidence Data are not defined in this document. Other specifications MUST define the contents and register for a Frame Type.

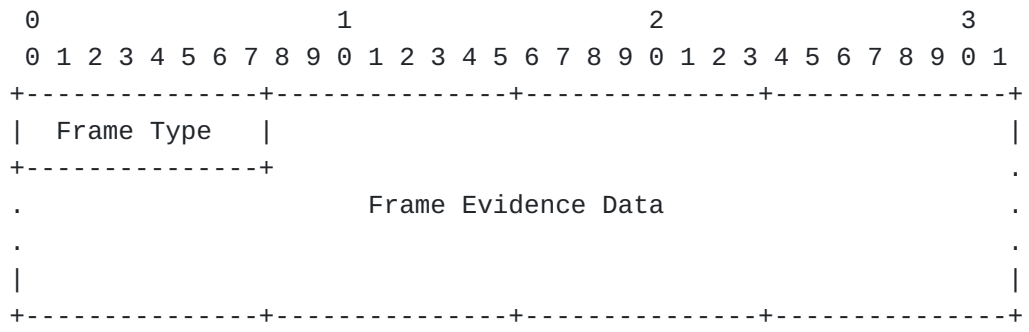

Figure 11: DRIP Frame

4.5.1. Frame Type

Byte to sub-type for future different DRIP Frame formats. It takes the first byte in Figure 11, leaving 111 bytes available for Frame Evidence Data. See Section 8.1 for Frame Type allocations.

5. Forward Error Correction

For Broadcast RID, Forward Error Correction (FEC) is provided by the lower layers in Extended Transports. The Bluetooth 4.x Legacy Transport does not have supporting FEC, so with DRIP Authentication the following application level FEC scheme is used to add FEC. When sending data over a medium that does not have underlying FEC, for example Bluetooth 4.x, then this section MUST be used.

The Bluetooth 4.x lower layers have error detection but not correction. Any frame in which Bluetooth detects an error is dropped and not delivered to higher layers (in our case, DRIP). Thus it can be treated as an erasure.

DRIP standardizes a single page FEC scheme using XOR parity across all page data of an Authentication Message. This allows the correction of single erased page in an Authentication Message. Other FEC schemes, to protect more than a single page of an Authentication Message or multiple [F3411] Messages, is left for future standardization if operational experience proves it necessary and/or practical.

The data added during FEC is not included in the Authentication Data / Signature, but instead in the Additional Data field of Figure 2. This may cause the Authentication Message to exceed 9-pages, up to a maximum of 16-pages.

5.1. Encoding

When encoding two things are REQUIRED:

1. The FEC data MUST start on a new Authentication Page. To do this, the results of parity encoding MUST be placed in the Additional Data field of Figure 2 with null padding before it to line up with the next page. The Additional Data Length field MUST be set to number of padding bytes + number of parity bytes.

2. The Last Page Index field (in Page 0) MUST be incremented from what it would have been without FEC by the number of pages required for the Additional Data Length field, null padding and FEC.

To generate the parity, a simple XOR operation using the previous parity page and current page is used. Only the 23-byte Authentication Payload field of Figure 1 is used in the XOR operations. For Page 0, a 23-byte null pad is used for the previous parity page.

Figure 12 shows an example of the last two pages (out of N) of an Authentication Message using DRIP Single Page FEC. The Additional Data Length is set to 33 as there are always 23 bytes of FEC data and in this example 10 bytes of padding to line it up into Page N.

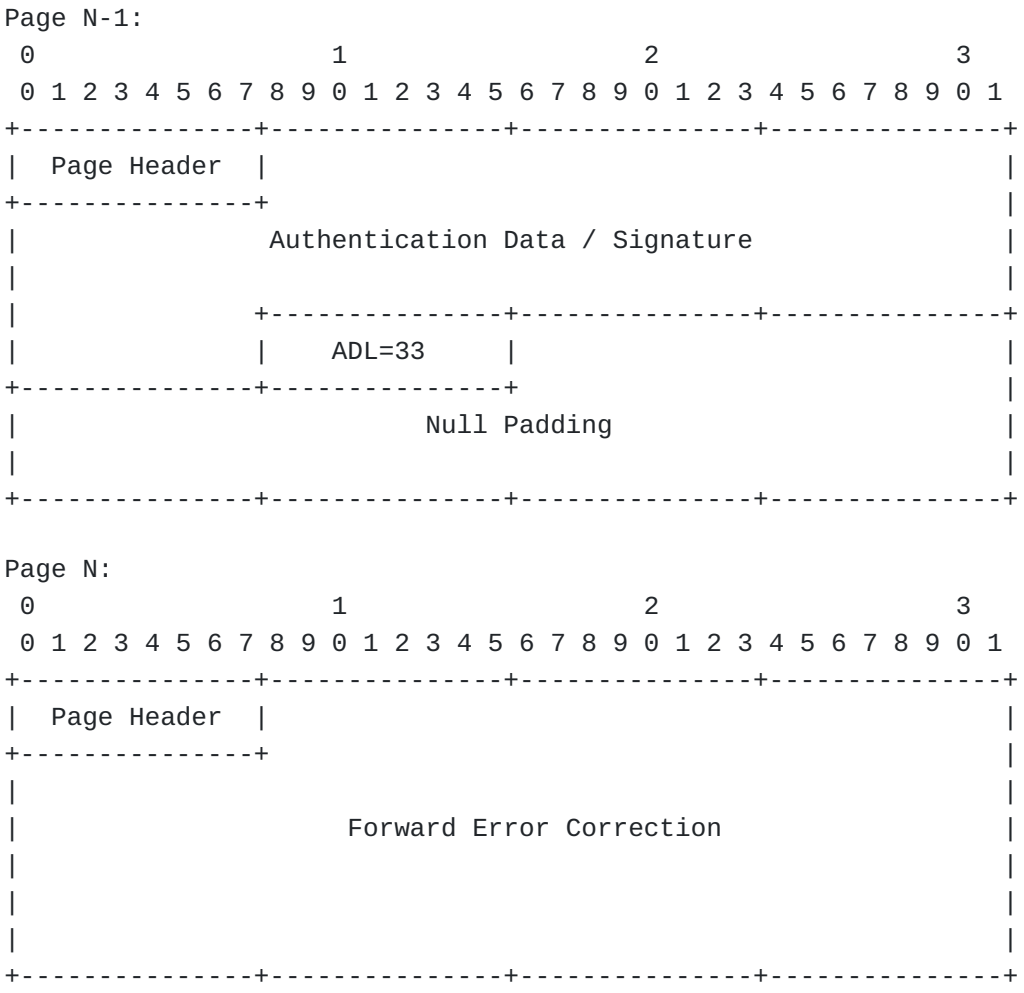

Figure 12: Example Single Page FEC Encoding

5.2. Decoding

To determine if FEC has been used, a simple check of the Last Page Index can be used. In general if the Last Page Index field is one greater than that necessary to hold Length bytes of Authentication Data then FEC has been used. Note however that if Length bytes was exhausted exactly at the end of an Authentication Page then the Additional Data Length field will occupy the first byte of the following page the remainder of which under DRIP will be null padded. In this case the Last Page Index will have been incremented once for initializing the Additional Data Length field and once for FEC page, for a total of two additional pages.

To decode FEC in DRIP, a rolling XOR is used on each Authentication Page received in the current Authentication Message. A Message Counter, outside of the ASTM Message but specified in [F3411], is used to signal a different Authentication Message and to correlate pages to messages. This Message Counter is only 1-byte in length, so it will roll over (to 0x00) after reaching its maximum value (0xFF).

If only 1-page is missing in the Authentication Message the resulting parity bytes should be the data of the erased page.

Authentication Page 0 contains various important fields, only located on that page, that help decode the full ASTM Authentication Message. If Page 0 has been reconstructed the Last Page Index and Length fields are REQUIRED to be sanity checked by DRIP. The pseudo-code in Figure 13 can be used for both checks.

```
function decode_check(auth_pages[], decoded_lpi, decoded_length) {
  // check decoded Last Page Index (LPI) does not exceed maximum LPI
  if (decoded_lpi >= 16) {
    return DECODE_FAILURE
  }

  // check that decoded length does not exceed DRIP maximum
  if (decoded_length > 201) {
    return DECODE_FAILURE
  }

  // grab the page at index where length ends and extract its data
  auth_data = auth_pages[(decoded_length - 17) / 23].data
  // find the index of last auth byte
  last_auth_byte = (17 + (23 * last_auth_page)) - decoded_length

  // look for non-nulls after the last auth byte
  if (auth_data[(last_auth_byte + 2):] has non-nulls) {
    return DECODE_FAILURE
  }

  // check that byte directly after last auth byte is null
  if (auth_data[last_auth_byte + 1] equals null) {
    return DECODE_FAILURE
  }

  // we set our presumed Additional Data Length (ADL)
  presumed_adl = auth_data[last_auth_byte + 1]
  // use the presumed ADL to calculate a presumed LPI
  presumed_lpi = (presumed_adl + decoded_length - 17) / 23

  // check that presumed LPI and decoded LPI match
  if (presumed_lpi not equal decoded_lpi) {
    return DECODE_FAILURE
  }
  return DECODE_SUCCESS
}
```

Figure 13: Pseudo-code for Decode Checks

5.3. FEC Limitations

The worst-case scenario is when the Authentication Data / Signature ends perfectly on a page (Page N-1). This means the Additional Data Length would start the next page (Page N) and have 22 bytes worth of null padding to align the FEC to begin at the start of the next page (Page N+1). In this scenario, an entire page (Page N) is being wasted just to carry the Additional Data Length. This should be avoided where possible to maintain efficiency.

6. Requirements & Recommendations

6.1. Legacy Transports

With Legacy Advertisements the goal is to attempt to bring reliable receipt of the paged Authentication Message. FEC (Section 5) MUST be used, per mandated RID rules (for example the US FAA RID Rule [FAA-14CFR]), when using Legacy Advertising methods (such as Bluetooth 4.x).

Under [F3411], Authentication Messages are transmitted at the static rate (at least every 3 seconds). Any DRIP Authentication Messages containing dynamic data (such as the DRIP Wrapper) MAY be sent at the dynamic rate (at least every 1 second).

6.2. Extended Transports

Under the ASTM specification, Extended Transports of RID must use the Message Pack (Message Type 0xF) format for all transmissions. Under Message Pack messages are sent together (in Message Type order) in a single frame (up to 9 single frame equivalent messages under Legacy Transports). Message Packs are required by [F3411] to be sent at a rate of 1 per second (like dynamic messages).

Without any fragmentation or loss of pages with transmission FEC (Section 5) MUST NOT be used as it is impractical.

6.3. Authentication

It is REQUIRED that a UA send the following DRIP Authentication Formats to fulfill the requirements in [RFC9153]:

1. SHOULD: send DRIP Link (Section 4.2) using the Broadcast Endorsement: Apex, RAA (satisfying GEN-3); at least once per 5 minutes

2. MUST: send DRIP Link (Section 4.2) using the Broadcast Endorsement: RAA, HDA (satisfying GEN-3); at least once per 5 minutes

3. MUST: send DRIP Link (Section 4.2) using the Broadcast Endorsement: HDA, UA (satisfying ID-5, GEN-1 and GEN-3); at least once per minute

4. MUST: send any other DRIP Authentication Format (RECOMMENDED: DRIP Manifest (Section 4.4) or DRIP Wrapper (Section 4.3)) where the UA is dynamically signing data that is guaranteed to be unique, unpredictable and easily cross checked by the receiving device (satisfying ID-5, GEN-1 and GEN-2); at least once per 5 seconds

6.4. Operational

UAS operation may impact the frequency of sending DRIP Authentication messages. When a UA dwells at an approximate location, and the channel is heavily used by other devices, less frequent message authentication may be sufficient for an Observer. Contrast this with a UA traversing an area, where every message should be authenticated as soon as possible for greatest success as viewed by the receiver.

Thus how/when these DRIP Authentication Messages are sent is up to each implementation. Further complication comes in comparing Legacy and Extended Transports. In Legacy, each message is a separate hash within the Manifest. So, when the UA remains within a small volume of airspace, it may lean toward occasional message authentication. In Extended Transports, the hash is over the Message Pack so only few hashes need to be in a Manifest. A single Manifest can handle a potential two Message Packs (for a full set of messages) and a DRIP Link Authentication Message for the Broadcast Endorsement: HDA, UA.

A separate issue is the frequency of transmitting the DRIP Link Authentication Message for the Broadcast Endorsement: HDA, UA when using the Manifest. This message content is static; its hash never changes radically. The only change is the 4-byte timestamp in the Authentication Message headers. Thus, potentially, in a dwell style operation it can be sent once per minute, where its hash is in every Manifest. A receiver can cache all DRIP Link Authentication Message for the Broadcast Endorsement: HDA, UA to mitigate potential packet loss.

The following operational configuration is RECOMMENDED (in alignment with Section 6.3):

1. Per CAA requirements, generate and transmit a set of ASTM Messages (example; Basic ID, Location and System).

2. Under Extended Transports, generate and include in the same Message Pack as the CAA required ASTM Messages a DRIP Wrapper

as specified in Section 4.3.2 (implicitly wrapping and signing messages in the pack).

3. Under Legacy Transports, generate and transmit every 5 seconds a DRIP Manifest (Section 4.4) hashing as many sets as desired of recent CAA required ASTM Messages. The system MAY periodically replace the DRIP Manifest with a DRIP Wrapper (Section 4.3) containing at least a Location Message (Message Type 0x2).

4. Under both Legacy or Extended Transports, generate and transmit a DRIP Link's (Section 4.2) containing; Broadcast Endorsement: HDA, UA every minute, Broadcast Endorsement: RAA, HDA every 5 minutes, Broadcast Endorsement: Apex, RAA every 5 minutes.

The reasoning and math behind these recommendations can be found in Appendix B.

6.4.1. DRIP Wrapper

The DRIP Wrapper MUST NOT be used in place of sending the ASTM messages as is. All receivers MUST be able to process all the messages specified in [F3411]. Sending them within the DRIP Wrapper makes them opaque to receivers lacking support for DRIP Authentication Messages. Thus, messages within a Wrapper are sent twice: in the clear and authenticated within the Wrapper. The DRIP Manifest would seem to be a more efficient use of the transport channel.

The DRIP Wrapper has a specific use case for DRIP aware receivers. For receiver plotting Location Messages (Message Type 0x2) on a map display an embedded Location Message in a DRIP Wrapper can be marked differently (e.g., via color) to signify trust in the Location data.

6.4.2. UAS RID Trust Assessment

As described in Section 3.1.4, the receiver MUST perform verification of the data being received in Broadcast RID. This is because trust in a key is different from trust that an observed UA possesses that key. A chain of DRIP Links provides trust in a key. A message containing rapidly changing, unpredictable but sanity-checkable data, signed by that key, provides trust that some agent with access to that data also possesses that key. If the sanity check involves correlating physical world observations of the UA with claims in that data, then the probability is high that the observed UA is (or is collaborating with or observed in real time by) the agent with the key.

After signature validation of any DRIP Authentication Message containing UAS RID information elements (e.g., DRIP Wrapper

Section 4.3) the Observer MUST use other sources of information to correlate against and perform verification. An example of another source of information is a visual confirmation of the UA position.

When correlation of these different data streams does not match in acceptable thresholds, the data SHOULD be rejected as if the signature failed to validate. Acceptable thresholds limits and what happens after such a rejection are out of scope for this document.

7. Summary of Addressed DRIP Requirements

The following [RFC9153] requirements are addressed in this document:

ID-5: Non-spoofability

> Addressed using the DRIP Wrapper (Section 4.3), DRIP Manifest (Section 4.4) or DRIP Frame (Section 4.5).

GEN-1: Provable Ownership

> Addressed using the DRIP Link (Section 4.2) and DRIP Wrapper (Section 4.3), DRIP Manifest (Section 4.4) or DRIP Frame (Section 4.5).

GEN-2: Provable Binding

> Addressed using the DRIP Wrapper (Section 4.3), DRIP Manifest (Section 4.4) or DRIP Frame (Section 4.5).

GEN-3: Provable Registration

> Addressed using the DRIP Link (Section 4.2).

8. IANA Considerations

8.1. IANA DRIP Registry

This document requests two new registries, for DRIP SAM Type and DRIP Frame Type, under the DRIP registry group.

DRIP SAM Type: This registry is a mirror for SAM Types containing the subset of allocations used by DRIP Authentication Messages. Future additions MUST be done through ICAO using their process. The following values have been allocated by ICAO to the IETF and are defined here:

SAM Type	Name	Description
0x01	DRIP Link	Format to hold Broadcast Endorsements
0x02	DRIP Wrapper	Authenticate full ASTM Messages
0x03	DRIP Manifest	Authenticate hashes of ASTM Messages
0x04	DRIP Frame	Format for future DRIP authentication

Figure 14: DRIP SAM Types

DRIP Frame Type: This 8-bit valued registry is for Frame Types in DRIP Frame Authentication Messages. Future additions to this registry are to be made through Expert Review (Section 4.5 of [RFC8126]). The following values are defined:

Frame Type	Name	Description
0x00	Reserved	Reserved
0xC0-0xFF	Experimental	Experimental Use

Figure 15: DRIP Frame Types

Criteria that should be applied by the designated experts includes determining whether the proposed registration duplicates existing functionality and whether the registration description is clear and fits the purpose of this registry.

Registration requests MUST be sent to drip-reg-review@ietf.org and be evaluated within a three-week review period on the advice of one or more designated experts. Within that review period, the designated experts will either approve or deny the registration request, and communicate their decision to the review list and IANA. Denials should include an explanation and, if applicable, suggestions to successfully register the prefix.

Registration requests that are undetermined for a period longer than 28 days can be brought to the IESG's attention for resolution.

9. Security Considerations

9.1. Replay Attacks

DRIP Link messages are static in nature. These DRIP Link messages can easily be replayed by an attacker who has copied them from previous broadcasts.

If an attacker (who is smart and spoofs more than just the UAS ID/ data payloads) willingly replays a DRIP Link message, they have in principle actually helped by ensuring the DRIP Link is sent more frequently and be received by potential Observers.

The primary mitigation is that the UA is REQUIRED to send more than DRIP Link messages, specifically the Manifest and/or Wrapper messages that sign over changing data ASTM Messages (e.g., Location/Vector Messages) using the DET private key. A UA sending these messages then actually signing these and other messages using the DET key provides the Observer with data that proves real-time signing. A UA that does not either run DRIP themselves or does not have possession of the same private key, would be clearly exposed upon signature verification.

9.2. VNA Timestamp Offsets for DRIP Authentication Formats

Note the discussion of VNA Timestamp offsets here is in the context of the DRIP Wrapper (Section 4.3), DRIP Manifest (Section 4.4), and DRIP Frame (Section 4.5). For DRIP Link (Section 4.2) these offsets are set by the DIME and have their own set of considerations in [drip-registries].

The offset of the VNA Timestamp by UA is one that needs careful consideration for any implementation. The offset should be shorter than any given flight duration (typically less than an hour) but be long enough to be received and processed by Observers (larger than a few seconds). It is recommended that 3-5 minutes should be sufficient to serve this purpose in any scenario, but is not limited by design.

10. Acknowledgments

*Ryan Quigley and James Mussi of AX Enterprize, LLC for early prototyping to find holes in the draft specifications.

*Soren Friis for pointing out that Wi-Fi implementations would not always give access to the MAC Address, originally used in calculation of the hashes for DRIP Manifest. Also, for confirming that Message Packs (0xF) can only carry up to 9 ASTM frames worth of data (9 Authentication pages).

*Thanks to the following reviewers:

-Rick Salz (secdir)

-Matt Joras (genart)

Appendix A. Authentication States

ASTM Authentication has only three states: None, Invalid, and Valid. This is because, under ASTM, the authentication is done by an external service hosted somewhere on the Internet so it is assumed an authoritative response will always be returned. This classification becomes more complex in DRIP with the support of "offline" scenarios where a receiver does not have Internet connectivity. With the use of asymmetric cryptography this means that the public key (PK) must somehow be obtained. [drip-registries] gets more into detail how these keys are stored on DNS and one use of DRIP Authentication messages is to send PK's over Broadcast RID.

There are a few keys of interest: the PK of the UA and the PK's of relevant DIMEs. This document describes how to send the PK of the UA over the Broadcast RID messages. The key of DIMEs are sent over Broadcast RID using the same mechanisms (see Section 4.2 and Section 6.3) but MAY be sent at a far lower rate due to potential operational constraints (such as saturation of limited bandwidth). As such, there are scenarios where part of the key-chain may be unavailable at the moment a full Authentication Message is received and processed.

The intent of this appendix is to give a recommended way to classify these various states and convey it to the user through colors and state names/text. These states can apply to either a single authentication message, a DET (and its associated public key), and/or a sender.

The table below lays out the RECOMMENDED colors to associate with state and a brief description of each.

State	Color	Details
None	Black	No Authentication being received (as yet)
Partial	Gray	Authentication being received but missing pages
Unsupported	Brown	Authentication Type/SAM Type of received message not supported
Unverifiable	Yellow	Data needed for signature verification is missing
Verified	Green	Valid verification results
Trusted	Blue	Valid verification results and DIME is marked as only registering DETs for trusted entities
Unverified	Red	Invalid verification results
Questionable	Orange	evidence of both Verified & Unverified for the same claimed sender
Conflicting	Purple	evidence of both Trusted & Unverified for the same claimed sender

Table 2: Authentication State Names, Colors & Descriptions

A.1. None: Black

The default state where no authentication information has yet to be received.

A.2. Partial: Gray

A pending state where authentication pages are being received but a full authentication message has yet to be compiled.

A.3. Unsupported: Brown

A state wherein authentication data is being or has been received, but cannot be used, as the Authentication Type or SAM Type is not supported by the receiver.

A.4. Unverifiable: Yellow

A pending state where a full authentication message has been received but other information, such as public keys to verify signatures, is missing.

A.5. Verified: Green

A state where all authentication messages that have been received, up to that point from that claimed sender, pass signature verification and the requirement of Section 6.4.2 has been met.

A.6. Trusted: Blue

A state where all authentication messages that have been received, up to that point, from that claimed sender, have passed signature verification, the requirement of Section 6.4.2 has been met, and the public key of the sending UA is marked as trusted.

The sending UA key will have been marked as trusted if the relevant DIMEs only register DETs (of subordinate DIMEs, UAS operators, and UA) that have been vetted as per their published registration policies, and those DIMEs have been marked, by the owner (individual or organizational) of the receiver, as per that owner's policy, as trusted to register DETs only for trusted parties.

A.7. Questionable: Orange

A state where there is a mix of authentication messages received that are Verified (Appendix A.5) and Unverified (Appendix A.8).

Transition to this state is from Verified if a subsequent message fails verification so would have otherwise been marked Unverified, or from Unverified if a subsequent message passes verification so

would otherwise have been marked Verified, or from either of those state upon mixed results on the requirement of Section 6.4.2.

A.8. Unverified: Red

A state where all authentication messages that have been received, up to that point, from that claimed sender, failed signature verification or the requirement of Section 6.4.2.

A.9. Conflicting: Purple

A state where there is a mix of authentication messages received that are Trusted (Appendix A.6) and Unverified (Appendix A.8) and the public key of the aircraft is marked as trusted.

Transition to this state is from Trusted if a subsequent message fails verification so would have otherwise been marked Unverified, or from Unverified if a subsequent message passes verification and policy checks so would otherwise have been marked Trusted, or from either of those state upon mixed results on the requirement of Section 6.4.2.

Appendix B. Operational Recommendation Analysis

The recommendations found in (Section 6.4) may seem heavy handed and specific. This appendix lays out the math and assumptions made to come to the recommendations listed there. This section is solely based on operations using Legacy Transports; as such, all calculations of frame counts for DRIP included FEC using Section 5.

B.1. Methodology

In the US, the required ASTM Messages to be transmitted every second are: Basic ID (0x1), Location (0x2), and System (0x4). Typical implementations will most likely send at a higher rate (2x sets per cycle) resulting in 6 frames sent per cycle. Transmitting this set of message more than once a second is not discouraged but awareness is needed to avoid congesting the RF spectrum, causing further issues.

> Informational Note: In Europe, the Operator ID Message (0x5) is also included; pushing the frame count to 8 per cycle. In Japan, two Basic ID (0x0), Location (0x1), and Authentication (0x2) are required, likely pushing the frame count beyond 8.

To calculate the frame count of a given DRIP Authentication Message the following formula is used:

```
1 + ceiling((((16 + 8 + 64) + (Item Size * Item Count) + 2) - 16)
/ 23) + 1
```

The leading 1 is counting for the Page 0 which is always present. The DET (16 bytes), timestamps (8 bytes) and signature (64 bytes) all make up the required fields for DRIP. Item Size (in bytes) is size of each item in a given format; for a Wrapper it is 25 (a full ASTM Message), while for a Manifest it is 8 (a single hash). 2 more is added to account for the SAM Type and the ADL byte. The value 16 is the number of bytes not counted (as they are part of Page 0 which is already counted for). 23 is the number of bytes per Authentication Page (pages 1 - 15). After dividing by 23 the value is raised to the nearest whole value as we can only send full frames, not partial. The final 1 is counting for a single page of FEC applied in DRIP under Bluetooth 4.x.

> Informational Note: for DRIP Link the Item Size is 48 and Item Count is 1; resulting in a frame count of 8

Comparing DRIP Wrapper and Manifest Authentication Message frame counts we have the following:

Authenticated Frames	**Wrapper Frames**	**Manifest Frames**	**Total Wrapper Frames**	**Total Manifest Frames**
1	7	7	8	8
2	8	7	10	9
3	9	7	12	10
4	10	8	14	12
5	N/A	8	N/A	13
6	N/A	8	N/A	14
7	N/A	9	N/A	16
8	N/A	9	N/A	17
9	N/A	10	N/A	19
10	N/A	10	N/A	20
11	N/A	10	N/A	21
12	N/A	12	N/A	24

Table 3: Frame Counts

Note that for Manifest Frames the calculations use an Item Count that is 2 + Authentication Frames. This is to account for the two special hashes.

The values in Total Frames is calculated by adding in the Item Count (to either the Wrapper Frames or Manifest Frames column) to account for the ASTM Messages being sent outside the Authentication Message.

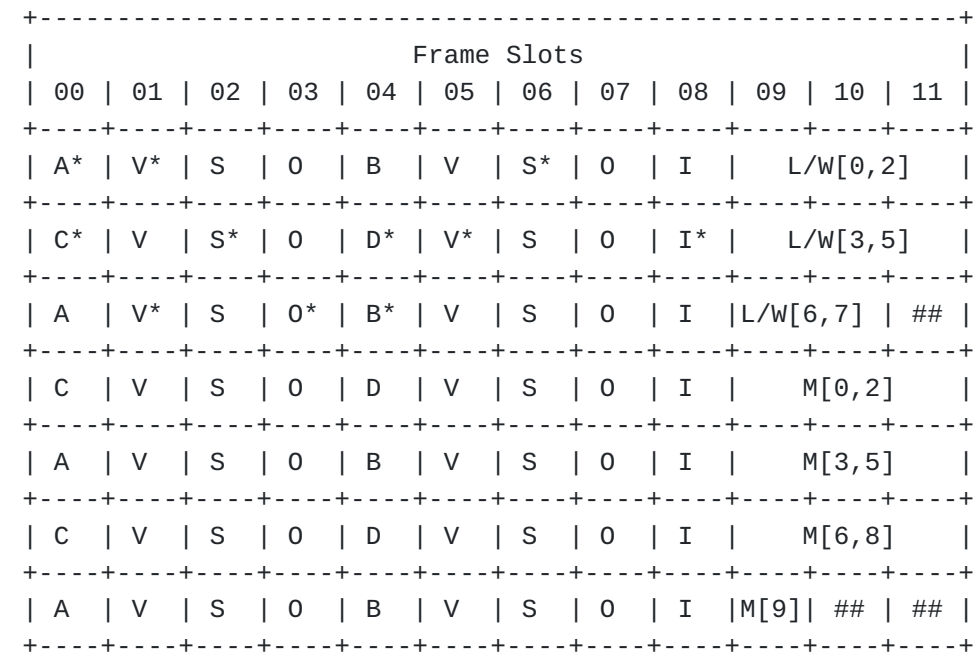
B.2. ASTM Maximum Schedule Example

For this example we will assume the following ASTM Messages are in play:

- *1x Basic ID (0x0) set as ID Type for Serial Number (0x1)
- *1x Basic ID (0x0) set as ID Type for CAA Assigned ID (0x2)
- *1x Basic ID (0x0) set as ID Type for UTM Assigned ID (0x3)
- *1x Basic ID (0x0) set as ID Type for Specific Session ID (0x4)
- *2x Location (0x1)
- *1x Self ID (0x3)
- *2x System (0x4)
- *2x Operator ID (0x5)

This message set uses all single frame ASTM Messages, sending a set of them (Location, System and Operator ID) at a rate of 2 per second. Two Basic IDs are sent in a single second and rotate between the 4 defined (1x per type). A single Self ID is sent every second. All messages in a given second, if appear more than once, are exact duplicates.

This example, as exactly presented here, would never make sense in practice, as a Single Use Session ID is pointless in conjunction with any other Basic ID. This is just to show that you *could* send everything, that doing so would have an overhead not much over 100%, and that you *could* create a reasonable practical schedule by simply "puncturing" this one (omitting those messages you don't need or want).



# = Empty Frame Slot
A = Basic ID Message (0x0) ID Type 1
B = Basic ID Message (0x0) ID Type 2
C = Basic ID Message (0x0) ID Type 3
D = Basic ID Message (0x0) ID Type 4
V = Location/Vector Message (0x1)
I = Self ID Message (0x3)
S = System Message (0x4)
O = Operator ID Message (0x5)

L[y,z] = DRIP Link Authentication Message (0x2)
W[y,z] = DRIP Wrapper Authentication Message (0x2)
  Wrapping Location (0x1) and System (0x4)
M[y,z] = DRIP Manifest Authentication Message (0x2)
  y = Start Page
  z = End Page
* = Message in DRIP Manifest Authentication Message

Figure 16: Example Legacy Transport Transmit Schedule

Manifest messages in the schedule are filled with unique messages from previously transmitted messages before the new Manifest is sent. In Figure 16, this is denoted by the * symbol as being part of the Manifest. In Figure 16, messages are eligible for the Manifest in the very first cycle of transmission. In future iterations, 56 messages are eligible across the 7 seconds it takes to send the previous Manifest and the next Link/Wrapper. Care should be given

into the selection of messages for a Manifest as there is a limit of 11 hashes.

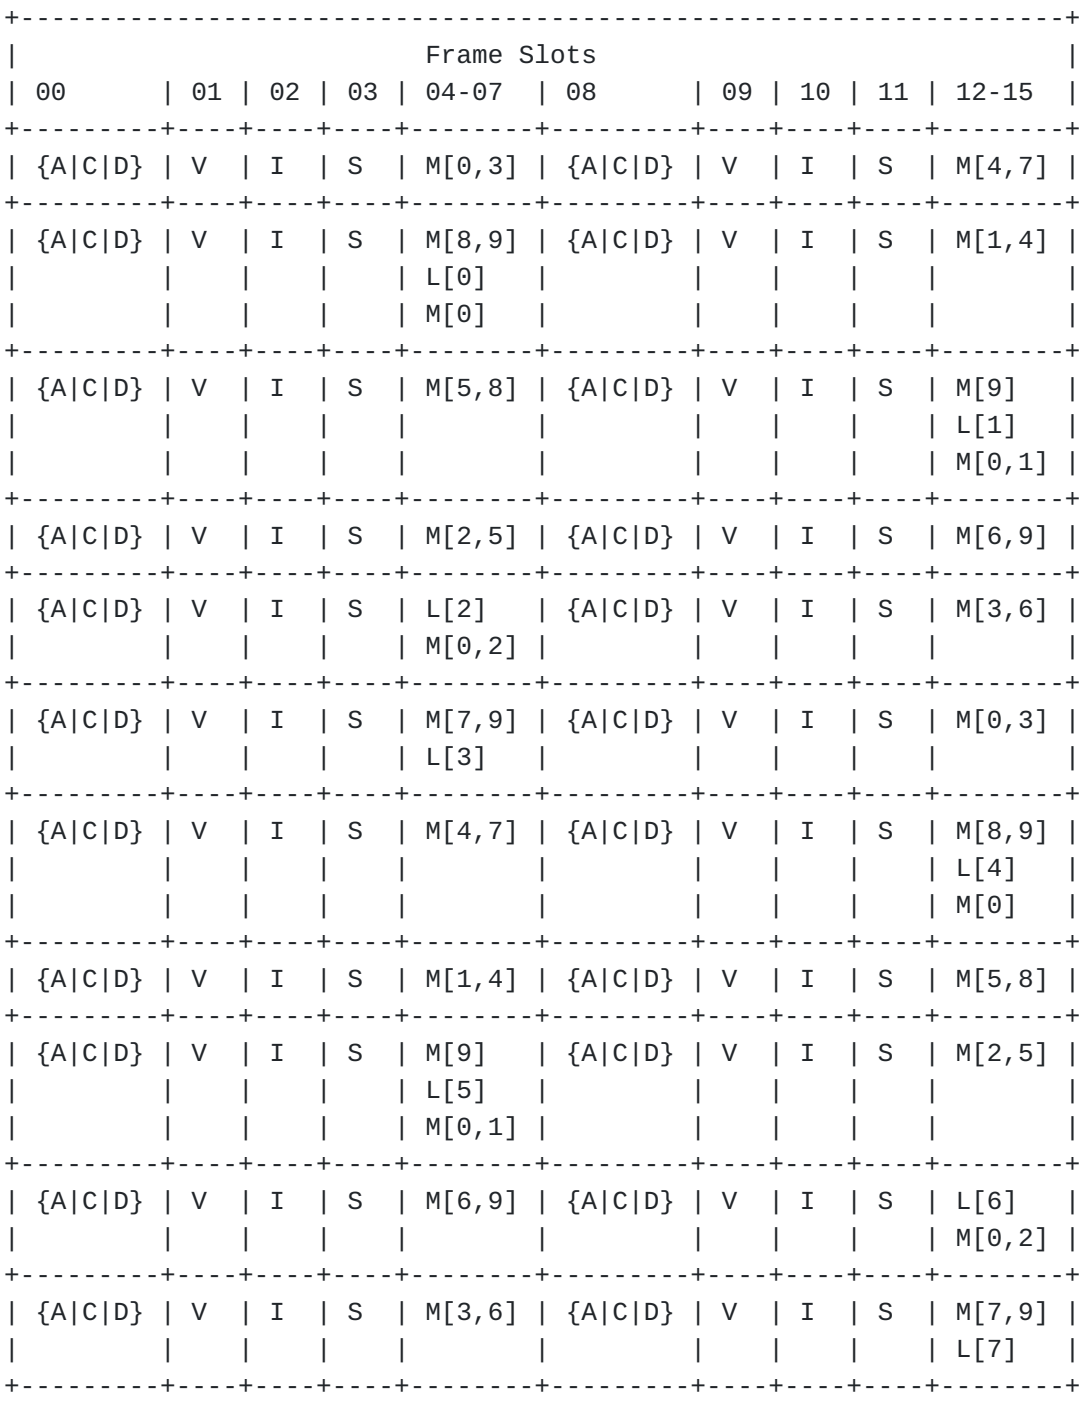
> Informational Note: the term "unique message" above is used as in the example schedule the 2nd Location and System messages MAY be exact copies of the previous Location and System messages sent in the same second. Duplicates of this kind SHOULD NOT be included in a Manifest.

In the schedule the Wrapper and the Link messages switch back and forth the contents of them are changing in the following order:

```
Link: HDA on UA
Link: RAA on HDA
Link: HDA on UA
Link: Apex on RAA
Link: HDA on UA
Link: RAA on HDA
Link: HDA on UA
Wrapper: Location (0x1), System (0x4)
Link: HDA on UA
Link: RAA on HDA
Link: HDA on UA
Link: Apex on RAA
Link: HDA on UA
Link: RAA on HDA
Link: HDA on UA
Wrapper: Location (0x1), System (0x4)
Link: IANA on UAS RID Apex
```

Any messages not required for a local jurisdiction can be removed from the schedule. It is RECOMMENDED this empty frame slot is left empty to help with timing due to RF constraints/concerns. For example, in the US the Self ID (0x3) and Operator ID (0x5) are not required and can be ignored in the above figures. Only one Basic ID (0x0) is selected in the US at any given time, opening up three (3) more slots.

B.3. US Example



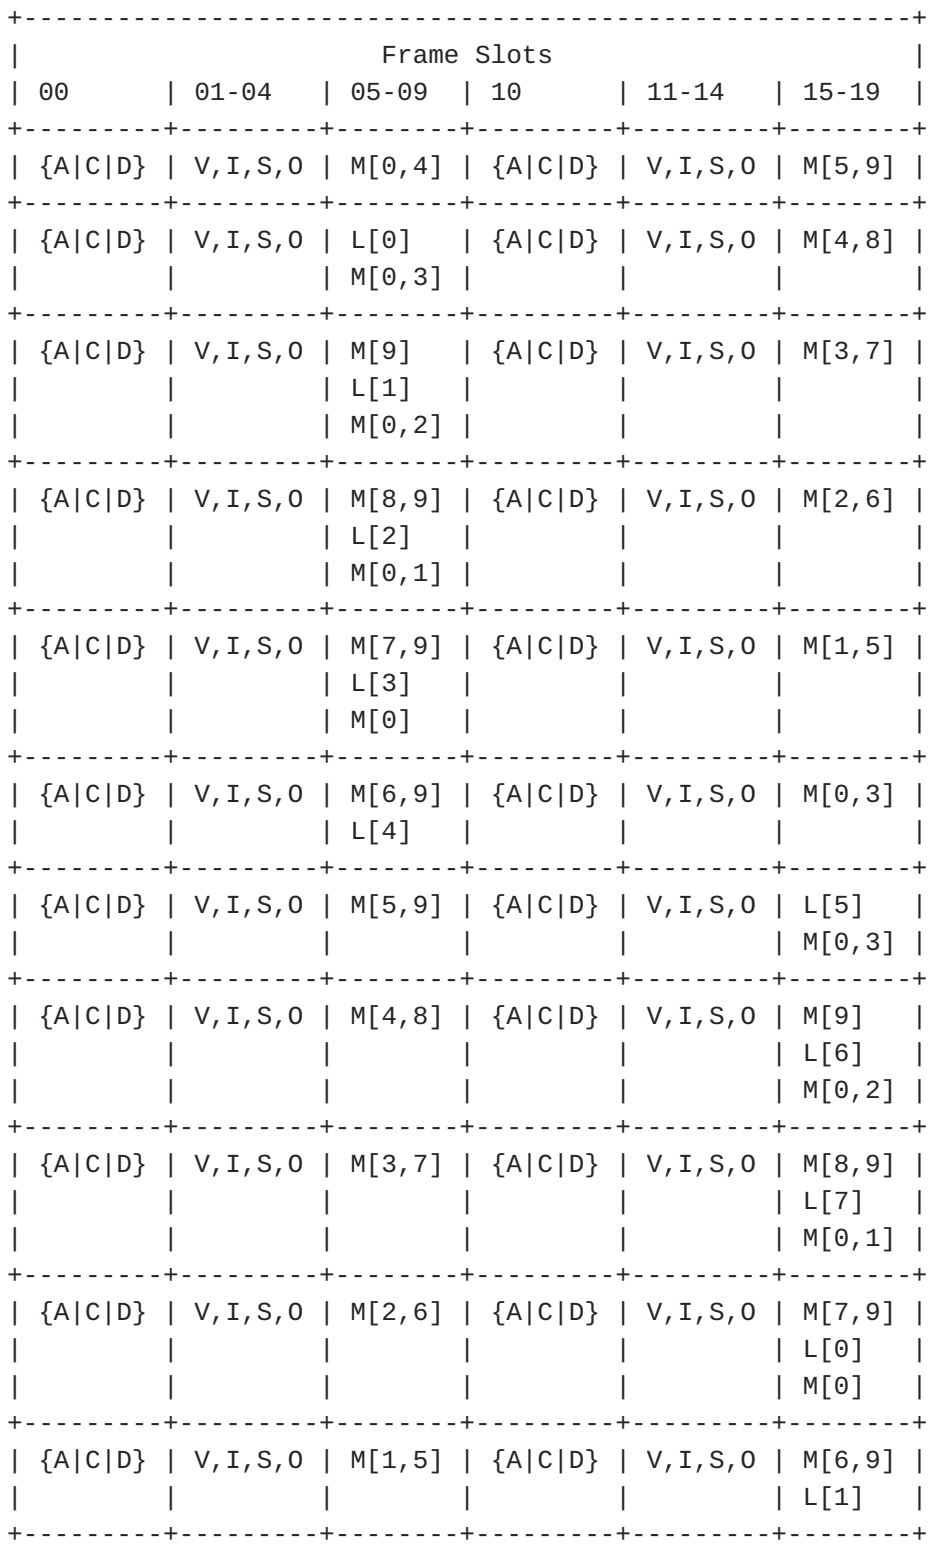
A = Basic ID Message (0x0) ID Type 1
C = Basic ID Message (0x0) ID Type 3
D = Basic ID Message (0x0) ID Type 4
V = Location/Vector Message (0x1)
I = Self ID Message (0x3)
S = System Message (0x4)

L[y,z] = DRIP Link Authentication Message (0x2)
M[y,z] = DRIP Manifest Authentication Message (0x2)

```
y = Start Page
z = End Page
```

Figure 17: US Example Legacy Transport Transmit Schedule

B.4. EU Example



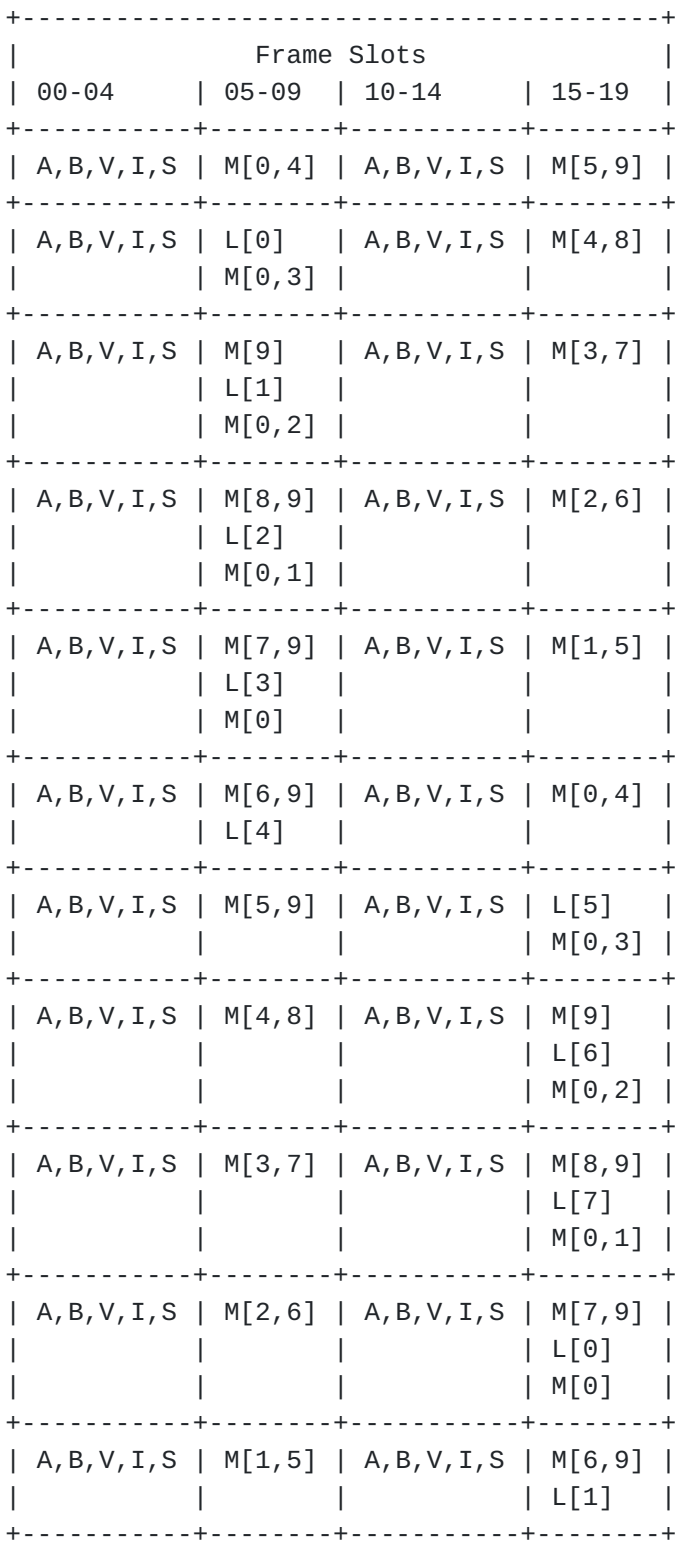
A = Basic ID Message (0x0) ID Type 1
C = Basic ID Message (0x0) ID Type 3
D = Basic ID Message (0x0) ID Type 4
V = Location/Vector Message (0x1)
I = Self ID Message (0x3)
S = System Message (0x4)

```
O = Operator ID Message (0x5)

L[y,z] = DRIP Link Authentication Message (0x2)
M[y,z] = DRIP Manifest Authentication Message (0x2)
  y = Start Page
  z = End Page
```

Figure 18: EU Example Legacy Transport Transmit Schedule

B.5. JP Example



A = Basic ID Message (0x0) ID Type 1
B = Basic ID Message (0x0) ID Type 2
V = Location/Vector Message (0x1)
I = Self ID Message (0x3)
S = System Message (0x4)

```
L[y,z] = DRIP Link Authentication Message (0x2)
M[y,z] = DRIP Manifest Authentication Message (0x2)
  y = Start Page
  z = End Page
```
