## **Delay-Tolerant Networking TCP Convergence Layer Protocol Version 4 draft-ietf-dtn-tcpclv4-05**

### Abstract

This document describes a revised protocol for the TCP-based convergence layer (TCPCL) for Delay-Tolerant Networking (DTN). The protocol revision is based on implementation issues in the original TCPCL Version 3 and updates to the Bundle Protocol contents, encodings, and convergence layer requirements in Bundle Protocol Version 7. Specifically, the TCPCLv4 uses CBOR-encoded BPv7 bundles as its service data unit being transported and provides a reliable transport of such bundles. Several new IANA registries are defined for TCPCLv4 which define some behaviors inherited from TCPCLv3 but with updated encodings and/or semantics.

### Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 17, 2018.

## [1.](#) Introduction

This document describes the TCP-based convergence-layer protocol for Delay-Tolerant Networking. Delay-Tolerant Networking is an end-to-end architecture providing communications in and/or through highly stressed environments, including those with intermittent connectivity, long and/or variable delays, and high bit error rates. More detailed descriptions of the rationale and capabilities of these networks can be found in "Delay-Tolerant Network Architecture" [[RFC4838](#)].

An important goal of the DTN architecture is to accommodate a wide range of networking technologies and environments. The protocol used for DTN communications is the revised Bundle Protocol (BP) [[I-D.ietf-dtn-bpbis](#)], an application-layer protocol that is used to construct a store-and-forward overlay network. As described in the Bundle Protocol specification [[I-D.ietf-dtn-bpbis](#)], it requires the services of a "convergence-layer adapter" (CLA) to send and receive bundles using the service of some "native" link, network, or Internet protocol. This document describes one such convergence-layer adapter that uses the well-known Transmission Control Protocol (TCP). This convergence layer is referred to as TCPCL.

The locations of the TCPCL and the BP in the Internet model protocol stack (described in [[RFC1122](#)]) are shown in Figure 1. In particular, when BP is using TCP as its bearer with TCPCL as its convergence layer, both BP and TCPCL reside at the application layer of the Internet model.

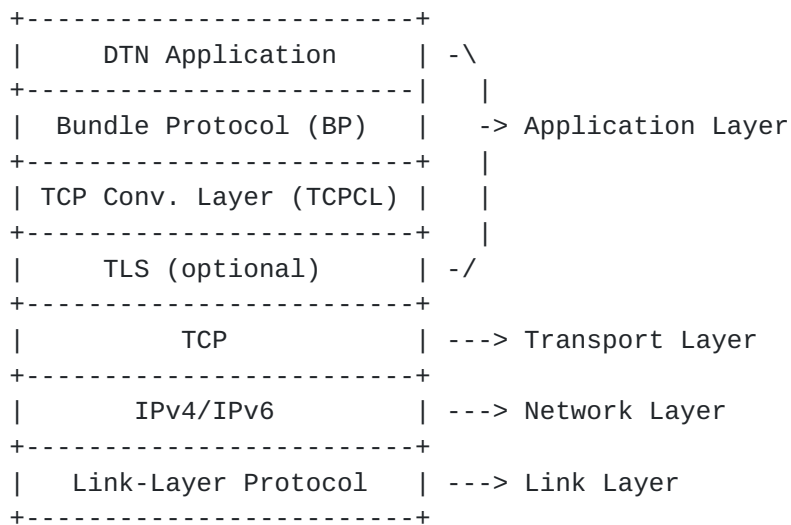

Figure 1: The Locations of the Bundle Protocol and the TCP Convergence-Layer Protocol above the Internet Protocol Stack

This document describes the format of the protocol data units passed between entities participating in TCPCL communications. This document does not address:

- o The format of protocol data units of the Bundle Protocol, as those are defined elsewhere in [[RFC5050](#)] and [[I-D.ietf-dtn-bpbis](#)]. This includes the concept of bundle fragmentation or bundle encapsulation. The TCPCL transfers bundles as opaque data blocks.
- o Mechanisms for locating or identifying other bundle nodes within an internet.

## 2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

### 2.1. Definitions Specific to the TCPCL Protocol

This section contains definitions that are interpreted to be specific to the operation of the TCPCL protocol, as described below.

**TCPCL Node:** A TCPCL node refers to either side of an negotiating or in-service TCPCL Session. For most TCPCL behavior, the two nodes are symmetric and there is no protocol distinction between them. Some specific behavior, particularly during negotiation, distinguishes between the connecting node and the connected-to

node. For the remainder of this document, the term "node" without the prefix "TCPCL" refers to a TCPCL node.

**TCP Connection:** A TCP connection refers to a transport connection using TCP as the transport protocol.

**TCPCL Session:** A TCPCL session (as opposed to a TCP connection) is a TCPCL communication relationship between two bundle nodes. The lifetime of a TCPCL session is bound to the lifetime of an underlying TCP connection. Therefore, a TCPCL session is initiated after a bundle node establishes a TCP connection to for the purposes of bundle communication. A TCPCL session is terminated when the TCP connection ends, due either to one or both nodes actively terminating the TCP connection or due to network errors causing a failure of the TCP connection. For the remainder of this document, the term "session" without the prefix "TCPCL" refers to a TCPCL session.

**Session parameters:** The session parameters are a set of values used to affect the operation of the TCPCL for a given session. The manner in which these parameters are conveyed to the bundle node and thereby to the TCPCL is implementation dependent. However, the mechanism by which two bundle nodes exchange and negotiate the values to be used for a given session is described in [Section 4.2](#).

**Transfer:** Transfer refers to the procedures and mechanisms (described below) for conveyance of an individual bundle from one node to another. Each transfer within TCPCLv4 is identified by a Transfer ID number which is unique only to a single direction within a single Session.

**Idle Session:** A TCPCL session is idle while the only messages being transmitted or received are KEEPALIVE messages.

**Lively Session:** A TCPCL session is lively while any messages are being transmitted or received.

**Reason Codes:** The TCPCL uses numeric codes to encode specific reasons for individual failure/error message types. This limits the expressiveness of TCPCL error encodings, but simplifies the encoding of errors and allows an application policy to attempt recovery from expected 'failure' modes (e.g. if a Session cannot be established with USE\_TLS disabled because of a Contact Failure shutdown, a re-attempt can be made with USE\_TLS enabled).

### **3. General Protocol Description**

The service of this protocol is the transmission of DTN bundles via the Transmission Control Protocol (TCP). This document specifies the encapsulation of bundles, procedures for TCP setup and teardown, and a set of messages and node requirements. The general operation of the protocol is as follows.

#### **3.1. TCPCL Session Overview**

First, one node establishes a TCPCL session to the other by initiating a TCP connection in accordance with [[RFC0793](#)]. After setup of the TCP connection is complete, an initial contact header is exchanged in both directions to set parameters of the TCPCL session and exchange a singleton endpoint identifier for each node (not the singleton Endpoint Identifier (EID) of any application running on the node) to denote the bundle-layer identity of each DTN node. This is used to assist in routing and forwarding messages (e.g. to prevent loops).

Once the TCPCL session is established and configured in this way, bundles can be transferred in either direction. Each transfer is performed by an initialization (XFER\_INIT) message followed by one or more logical segments of data within an XFER\_SEGMENT message. The choice of the length to use for segments is an implementation matter, but each segment must be no larger than the receiving node's maximum receive unit (MRU) (see the field "Segment MRU" of [Section 4.1](#)). The first segment for a bundle MUST set the 'START' flag, and the last one MUST set the 'end' flag in the XFER\_SEGMENT message flags.

If multiple bundles are transmitted on a single TCPCL connection, they MUST be transmitted consecutively. Interleaving data segments from different bundles is not allowed. Bundle interleaving can be accomplished by fragmentation at the BP layer or by establishing multiple TCPCL sessions.

A feature of this protocol is for the receiving node to send acknowledgments as bundle data segments arrive (XFER\_ACK). The rationale behind these acknowledgments is to enable the sender node to determine how much of the bundle has been received, so that in case the session is interrupted, it can perform reactive fragmentation to avoid re-sending the already transmitted part of the bundle. For each data segment that is received, the receiving node sends an XFER\_ACK message containing the cumulative length of the bundle that has been received. The sending node MAY transmit multiple XFER\_SEGMENT messages without necessarily waiting for the corresponding XFER\_ACK responses. This enables pipelining of

messages on a channel. In addition, there is no explicit flow control on the TCPCL layer.

Another feature is that a receiver MAY interrupt the transmission of a bundle at any point in time by replying with a XFER\_REFUSE message, which causes the sender to stop transmission of the current bundle, after completing transmission of a partially sent data segment.

Note: This enables a cross-layer optimization in that it allows a receiver that detects that it already has received a certain bundle to interrupt transmission as early as possible and thus save transmission capacity for other bundles.

For sessions that are idle, a KEEPALIVE message is sent at a negotiated interval. This is used to convey node liveness information during otherwise message-less time intervals.

Finally, before sessions close, a SHUTDOWN message is sent to the session peer (see [Section 6.1](#)). After sending a SHUTDOWN message, the peer can not initiate any further transfers and the session enters a closing-down phase. After receiving a SHUTDOWN message and when no transfers are in-progress (i.e. have pending or unacknowledged segments), the receiving peer can close the session without chance of lost transfers. A SHUTDOWN message can also be used to refuse a session setup by a peer (see [Section 4.2](#)). It is an implementation matter to determine whether or not to close a TCPCL session while there are no transfers queued or in-progress.

There are specific messages for sending and receiving operations (in addition to session setup/teardown). TCPCL is symmetric, i.e., both sides can start sending data segments in a session, and one side's bundle transfer does not have to complete before the other side can start sending data segments on its own. Hence, the protocol allows for a bi-directional mode of communication. Note that in the case of concurrent bidirectional transmission, acknowledgment segments MAY be interleaved with data segments.

### **[3.2.](#) Example Message Exchange**

The following figure depicts the protocol exchange for a simple session, showing the session establishment and the transmission of a single bundle split into three data segments (of lengths "L1", "L2", and "L3") from Node A to Node B.

Note that the sending node MAY transmit multiple XFER\_SEGMENT messages without necessarily waiting for the corresponding XFER\_ACK responses. This enables pipelining of messages on a channel. Although this example only demonstrates a single bundle transmission, it is also possible to pipeline multiple XFER\_SEGMENT messages for

different bundles without necessarily waiting for XFER\_ACK messages to be returned for each one. However, interleaving data segments from different bundles is not allowed.

No errors or rejections are shown in this example.

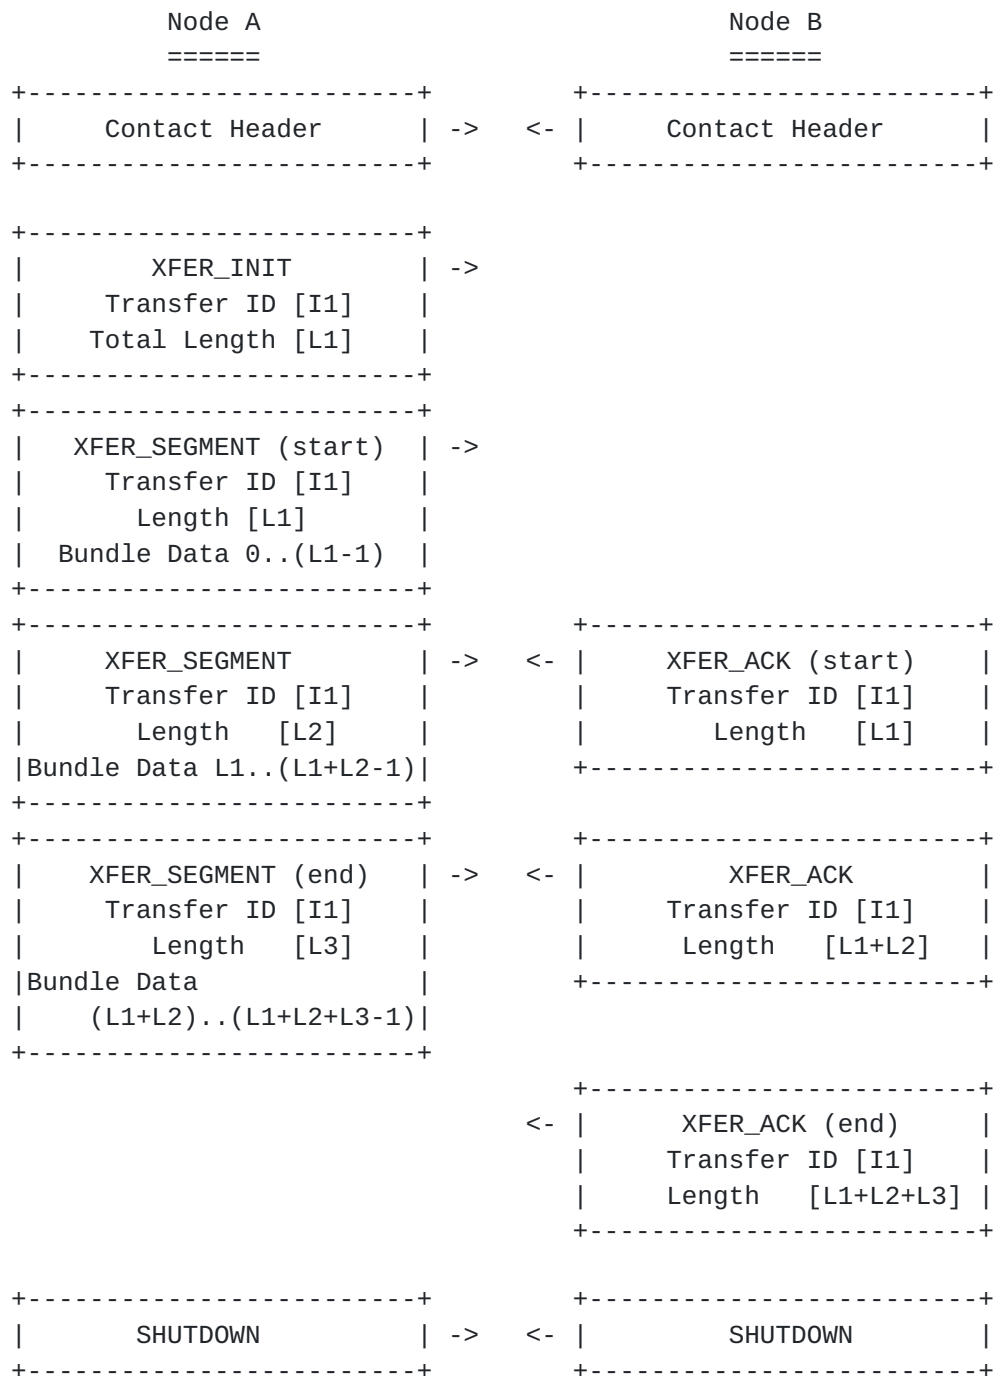

Figure 2: An Example of the Flow of Protocol Messages on a Single TCP Session between Two Nodes (A and B)

#### **4. Session Establishment**

For bundle transmissions to occur using the TCPCL, a TCPCL session **MUST** first be established between communicating nodes. It is up to the implementation to decide how and when session setup is triggered. For example, some sessions **MAY** be opened proactively and maintained for as long as is possible given the network conditions, while other sessions **MAY** be opened only when there is a bundle that is queued for transmission and the routing algorithm selects a certain next-hop node.

To establish a TCPCL session, a node **MUST** first establish a TCP connection with the intended peer node, typically by using the services provided by the operating system. Destination port number 4556 has been assigned by IANA as the Registered Port number for the TCP convergence layer. Other destination port numbers **MAY** be used per local configuration. Determining a peer's destination port number (if different from the registered TCPCL port number) is up to the implementation. Any source port number **MAY** be used for TCPCL sessions. Typically an operating system assigned number in the TCP Ephemeral range (49152--65535) is used.

If the node is unable to establish a TCP connection for any reason, then it is an implementation matter to determine how to handle the connection failure. A node **MAY** decide to re-attempt to establish the connection. If it does so, it **MUST NOT** overwhelm its target with repeated connection attempts. Therefore, the node **MUST** retry the connection setup only after some delay (a 1-second minimum is **RECOMMENDED**), and it **SHOULD** use a (binary) exponential backoff mechanism to increase this delay in case of repeated failures. In case a SHUTDOWN message specifying a reconnection delay is received, that delay is used as the initial delay. The default initial delay **SHOULD** be at least 1 second but **SHOULD** be configurable since it will be application and network type dependent.

The node **MAY** declare failure after one or more connection attempts and **MAY** attempt to find an alternate route for bundle data. Such decisions are up to the higher layer (i.e., the BP).

Once a TCP connection is established, each node **MUST** immediately transmit a contact header over the TCP connection. The format of the contact header is described in [Section 4.1](#).

Upon receipt of the contact header, both nodes perform the validation and negotiation procedures defined in [Section 4.2](#)

After receiving the contact header from the other node, either node **MAY** also refuse the session by sending a SHUTDOWN message. If

session setup is refused, a reason **MUST** be included in the SHUTDOWN message.

#### 4.1. Contact Header

Once a TCP connection is established, both parties exchange a contact header. This section describes the format of the contact header and the meaning of its fields.

The format for the Contact Header is as follows:

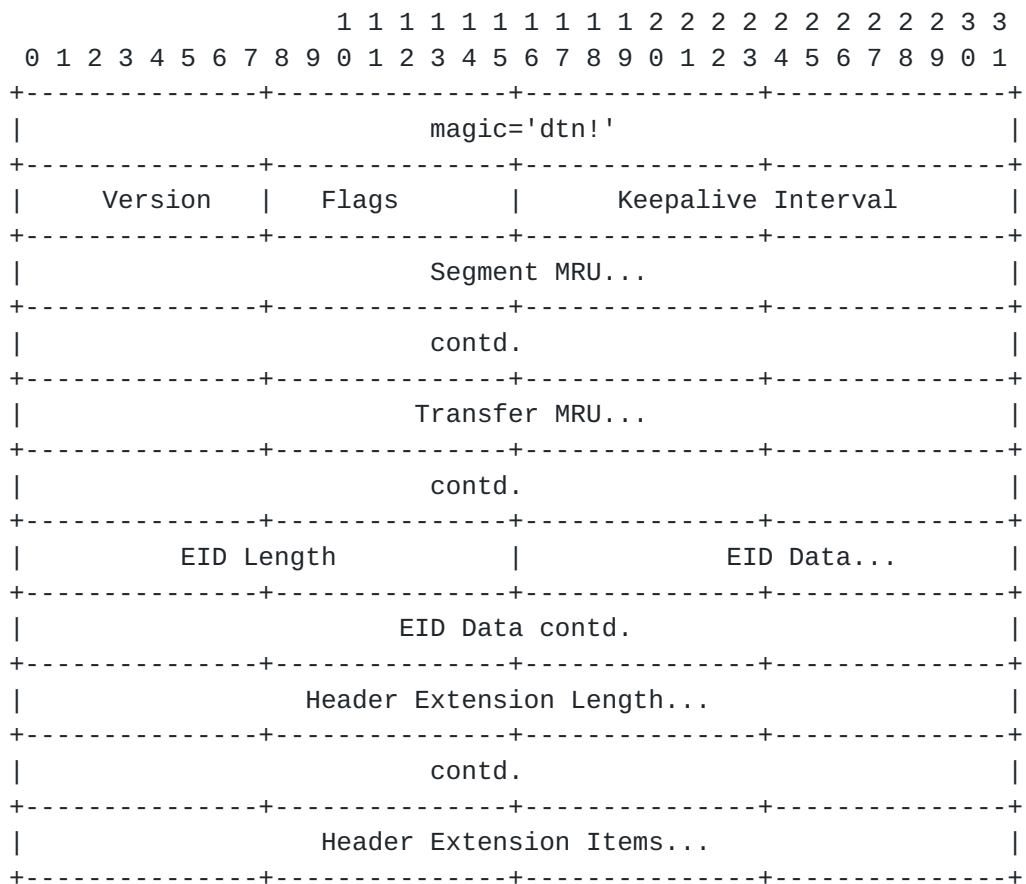

Figure 3: Contact Header Format

See [Section 4.2](#) for details on the use of each of these contact header fields. The fields of the contact header are:

**magic:** A four-octet field that always contains the octet sequence 0x64 0x74 0x6e 0x21, i.e., the text string "dtn!" in US-ASCII (and UTF-8).

**Version:** A one-octet field value containing the value 4 (current version of the protocol).

**Flags:** A one-octet field of single-bit flags, interpreted according to the descriptions in Table 1.

**Keepalive Interval:** A 16-bit unsigned integer indicating the interval, in seconds, between any subsequent messages being transmitted by the peer. The peer receiving this contact header uses this interval to determine how long to wait after any last-message transmission and a necessary subsequent KEEPALIVE message transmission.

**Segment MRU:** A 64-bit unsigned integer indicating the largest allowable single-segment data payload size to be received in this session. Any XFER\_SEGMENT sent to this peer SHALL have a data payload no longer than the peer's Segment MRU. The two nodes of a single session MAY have different Segment MRUs, and no relation between the two is required.

**Transfer MRU:** A 64-bit unsigned integer indicating the largest allowable total-bundle data size to be received in this session. Any bundle transfer sent to this peer SHALL have a Total bundle data payload no longer than the peer's Transfer MRU. This value can be used to perform proactive bundle fragmentation. The two nodes of a single session MAY have different Transfer MRUs, and no relation between the two is required.

**EID Length and EID Data:** Together these fields represent a variable-length text string. The EID Length is a 16-bit unsigned integer indicating the number of octets of EID Data to follow. A zero EID Length SHALL be used to indicate the lack of EID rather than a truly empty EID. This case allows an node to avoid exposing EID information on an untrusted network. A non-zero-length EID Data SHALL contain the UTF-8 encoded EID of some singleton endpoint in which the sending node is a member, in the canonical format of <scheme name>:<scheme-specific part>. This EID encoding is consistent with [[I-D.ietf-dtn-bpbis](#)].

**Header Extension Length Header Extension Items:** Together these fields represent protocol extension data not defined by this specification. The Header Extension Length is the total number of octets to follow which are used to encode the Header Extension Item list. The encoding of each Header Extension Item is identical form as described in [Section 4.1.1](#).

Name	Code	Description
CAN_TLS	0x01	If bit is set, indicates that the sending peer is capable of TLS security.
Reserved	others	

Table 1: Contact Header Flags

#### 4.1.1. Header Extension Items

Each of the Header Extension items SHALL be encoded in an identical Type-Length-Value (TLV) container form as indicated in Figure 4. The fields of the header extension item are:

**Flags:** A one-octet field containing generic bit flags about the item, which are listed in Table 2. If a TCPCL node receives an extension item with an unknown Item Type and the CRITICAL flag set, the node SHALL close the TCPCL session with SHUTDOWN reason code of "Contact Failure". If the CRITICAL flag is not set, a node SHALL skip over and ignore any item with an unknown Item Type.

**Item Type:** A 16-bit unsigned integer field containing the type of the extension item. This specification does not define any extension types directly, but does allocate an IANA registry for such codes (see [Section 8.3](#)).

**Item Length:** A 32-bit unsigned integer field containing the number of Item Value octets to follow.

**Item Value:** A variable-length data field which is interpreted according to the associated Item Type. This specification places no restrictions on an extensions use of available Item Value data. Extension specification SHOULD avoid the use of large data exchanges within the TCPCLv4 contact header as no bundle transfers can begin until the a full contact exchange and negotiation has been completed.

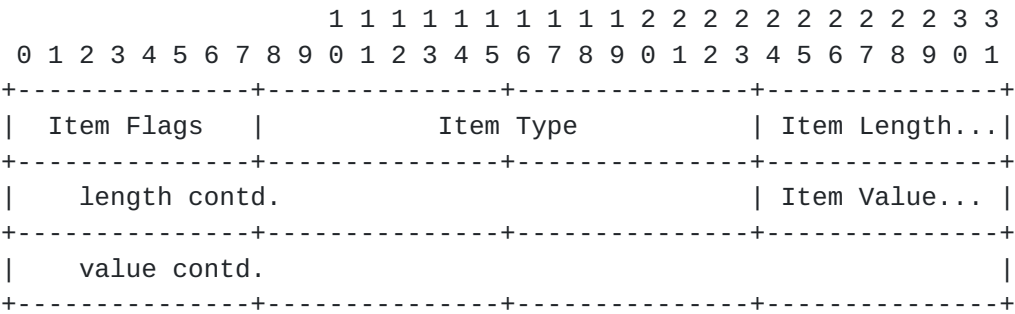

Figure 4: Header Extention Item Format

Name	Code	Description
CRITICAL	0x01	If bit is set, indicates that the receiving peer must handle the extension item.
Reserved	others	

Table 2: Header Extension Item Flags

4.2. Validation and Parameter Negotiation

Upon reception of the contact header, each node follows the following procedures to ensure the validity of the TCPCL session and to negotiate values for the session parameters.

If the magic string is not present or is not valid, the connection MUST be terminated. The intent of the magic string is to provide some protection against an inadvertent TCP connection by a different protocol than the one described in this document. To prevent a flood of repeated connections from a misconfigured application, a node MAY elect to hold an invalid connection open and idle for some time before closing it.

A connecting TCPCL node SHALL send the highest TCPCL protocol version on a first session attempt for a TCPCL peer. If a connecting node receives a SHUTDOWN message with reason of "Version Mismatch", that node MAY attempt further TCPCL sessions with the peer using earlier protocol version numbers in decreasing order. Managing multi-TCPCL-session state such as this is an implementation matter.

If a node receives a contact header containing a version that is greater than the current version of the protocol that the node implements, then the node SHALL shutdown the session with a reason code of "Version mismatch". If a node receives a contact header with

a version that is lower than the version of the protocol that the node implements, the node MAY either terminate the session (with a reason code of "Version mismatch"). Otherwise, the node MAY adapt its operation to conform to the older version of the protocol. The decision of version fall-back is an implementation matter.

A node calculates the parameters for a TCPCL session by negotiating the values from its own preferences (conveyed by the contact header it sent to the peer) with the preferences of the peer node (expressed in the contact header that it received from the peer). The negotiated parameters defined by this specification are described in the following paragraphs.

**Session Keepalive:** Negotiation of the Session Keepalive parameter is performed by taking the minimum of this two contact headers' Keepalive Interval. If the negotiated Session Keepalive is zero (i.e. one or both contact headers contains a zero Keepalive Interval), then the keepalive feature (described in [Section 5.2.1](#)) is disabled. There is no logical minimum value for the keepalive interval, but when used for many sessions on an open, shared network a short interval could lead to excessive traffic. For shared network use, nodes SHOULD choose a keepalive interval no shorter than 30 seconds. There is no logical maximum value for the keepalive interval, but an idle TCP connection is liable for closure by the host operating system if the keepalive time is longer than tens-of-minutes. Nodes SHOULD choose a keepalive interval no longer than 10 minutes (600 seconds).

**Enable TLS:** Negotiation of the Enable TLS parameter is performed by taking the logical AND of the two contact headers' CAN\_TLS flags. If the negotiated Enable TLS value is true then TLS negotiation feature (described in [Section 4.3](#)) begins immediately following the contact header exchange. The security policy on either node MAY forbid the establishment of a TCPCL session for any Enable TLS result (or for any combination of local or peer CAN\_TLS flag), in which case the node SHALL shutdown the session with a reason code of "Contact Failure". For example, one node may disallow TCPCL sessions without TLS, while a second node may disallow sessions with TLS. Also note that this Contact Failure (of the header negotiation) is different than a TLS Failure (after an agreed-upon Enable TLS state).

Once this process of parameter negotiation is completed (which includes a possible completed TLS handshake of the connection to use TLS), this protocol defines no additional mechanism to change the parameters of an established session; to effect such a change, the TCPCL session MUST be terminated and a new session established.

### **4.3. Session Security**

This version of the TCPCL supports establishing a Transport Layer Security (TLS) session within an existing TCP connection. Negotiation of whether or not to initiate TLS within a TCPCL session is part of the contact header as described in [Section 4.2](#). The TLS handshake, if it occurs, is considered to be part of the contact negotiation before the TCPCL session itself is established. Specifics about sensitive data exposure are discussed in [Section 7](#).

When TLS is used within the TCPCL it affects the entire session. By convention, this protocol uses the node which initiated the underlying TCP connection as the "client" role of the TLS handshake request. Once a TLS session is established within TCPCL, there is no mechanism provided to end the TLS session and downgrade the session. If a non-TLS session is desired after a TLS session is started then the entire TCPCL session MUST be shutdown first.

After negotiating an Enable TLS parameter of true, and before any other TCPCL messages are sent within the session, the session nodes SHALL begin a TLS handshake in accordance with [\[RFC5246\]](#). The parameters within each TLS nqion are implementation dependent but any TCPCL node SHOULD follow all recommended best practices of [\[RFC7525\]](#).

#### **4.3.1. TLS Handshake Result**

If a TLS handshake cannot negotiate a TLS session, both nodes of the TCPCL session SHALL cause a TCPCL shutdown with reason "TLS Failure".

After a TLS session is successfully established, both TCPCL nodes SHALL re-exchange TCPCL Contact Header messages. Any information cached from the prior Contact Header exchange SHALL be discarded. This re-exchange avoids man-in-the-middle attack in identical fashion to [\[RFC2595\]](#). Each re-exchange header CAN\_TLS flag SHALL be identical to the original header CAN\_TLS flag from the same node. The CAN\_TLS logic (TLS negotiation) SHALL NOT apply during header re-exchange. This reinforces the fact that there is no TLS downgrade mechanism.

#### **4.3.2. Example TLS Initiation**

A summary of a typical CAN\_TLS usage is shown in the sequence in Figure 5 below.

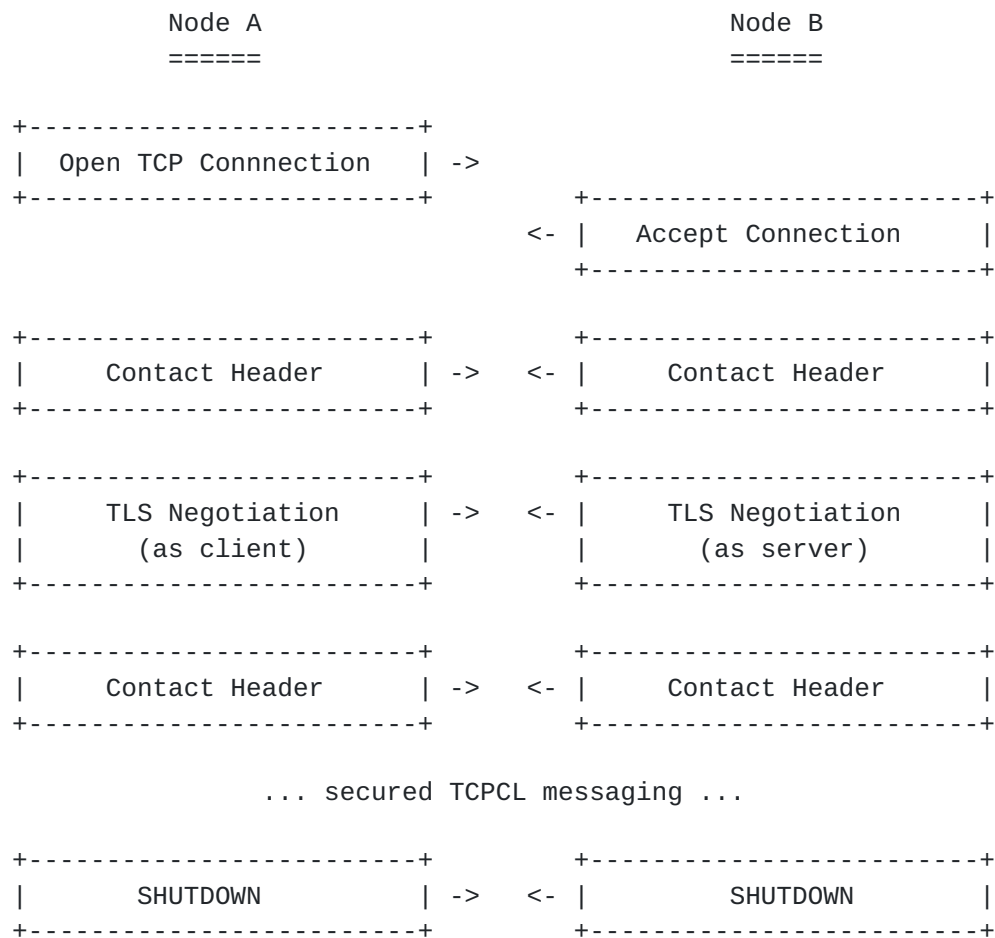

Figure 5: A simple visual example of TCPCL TLS Establishment between two nodes

## 5. Established Session Operation

This section describes the protocol operation for the duration of an established session, including the mechanism for transmitting bundles over the session.

### 5.1. Message Type Codes

After the initial exchange of a contact header, all messages transmitted over the session are identified by a one-octet header with the following structure:

```

 0 1 2 3 4 5 6 7
+-----+
| Message Type |
+-----+

```

Figure 6: Format of the Message Header

The message header fields are as follows:

Message Type: Indicates the type of the message as per Table 3 below. Encoded values are listed in [Section 8.4](#).

Type	Description
XFER_INIT	Contains the length (in octets) of the next transfer, as described in <a href="#">Section 5.3.2</a> .
XFER_SEGMENT	Indicates the transmission of a segment of bundle data, as described in <a href="#">Section 5.3.3</a> .
XFER_ACK	Acknowledges reception of a data segment, as described in <a href="#">Section 5.3.4</a> .
XFER_REFUSE	Indicates that the transmission of the current bundle SHALL be stopped, as described in <a href="#">Section 5.3.5</a> .
KEEPALIVE	Used to keep TCPCL session active, as described in <a href="#">Section 5.2.1</a> .
SHUTDOWN	Indicates that one of the nodes participating in the session wishes to cleanly terminate the session, as described in <a href="#">Section 6</a> .
MSG_REJECT	Contains a TCPCL message rejection, as described in <a href="#">Section 5.2.2</a> .

Table 3: TCPCL Message Types

## [5.2.](#) Upkeep and Status Messages

### [5.2.1.](#) Session Upkeep (KEEPALIVE)

The protocol includes a provision for transmission of KEEPALIVE messages over the TCPCL session to help determine if the underlying TCP connection has been disrupted.

As described in [Section 4.1](#), one of the parameters in the contact header is the Keepalive Interval. Both sides populate this field with their requested intervals (in seconds) between KEEPALIVE messages.

The format of a KEEPALIVE message is a one-octet message type code of KEEPALIVE (as described in Table 3) with no additional data. Both sides SHOULD send a KEEPALIVE message whenever the negotiated interval has elapsed with no transmission of any message (KEEPALIVE or other).

If no message (KEEPALIVE or other) has been received for at least twice the Keepalive Interval, then either party MAY terminate the session by transmitting a one-octet SHUTDOWN message (as described in [Section 6.1](#)) with reason code "Idle Timeout", and by closing the session.

Note: The Keepalive Interval SHOULD not be chosen too short as TCP retransmissions MAY occur in case of packet loss. Those will have to be triggered by a timeout (TCP retransmission timeout (RTO)), which is dependent on the measured RTT for the TCP connection so that KEEPALIVE messages MAY experience noticeable latency.

### 5.2.2. Message Rejection (MSG\_REJECT)

If a TCPCL node receives a message which is unknown to it (possibly due to an unhandled protocol mismatch) or is inappropriate for the current session state (e.g. a KEEPALIVE message received after contact header negotiation has disabled that feature), there is a protocol-level message to signal this condition in the form of a MSG\_REJECT reply.

The format of a MSG\_REJECT message follows:

```

+-----+
|      Message Header      |
+-----+
|      Reason Code (U8)    |
+-----+
|  Rejected Message Header  |
+-----+
```

Figure 7: Format of MSG\_REJECT Messages

The fields of the MSG\_REJECT message are:

Reason Code: A one-octet refusal reason code interpreted according to the descriptions in Table 4.

Rejected Message Header: The Rejected Message Header is a copy of the Message Header to which the MSG\_REJECT message is sent as a response.

Name	Code	Description
Message Type Unknown	0x01	A message was received with a Message Type code unknown to the TCPCL node.
Message Unsupported	0x02	A message was received but the TCPCL node cannot comply with the message contents.
Message Unexpected	0x03	A message was received while the session is in a state in which the message is not expected.

Table 4: MSG\_REJECT Reason Codes

### 5.3. Bundle Transfer

All of the message in this section are directly associated with transferring a bundle between TCPCL nodes.

A single TCPCL transfer results in a bundle (handled by the convergence layer as opaque data) being exchanged from one node to the other. In TCPCL a transfer is accomplished by dividing a single bundle up into "segments" based on the receiving-side Segment MRU (see [Section 4.1](#)).

A single transfer (and by extension a single segment) SHALL NOT contain data of more than a single bundle. This requirement is imposed on the agent using the TCPCL rather than TCPCL itself.

#### 5.3.1. Bundle Transfer ID

Each of the bundle transfer messages contains a Transfer ID number which is used to correlate messages originating from sender and receiver of a bundle. A Transfer ID does not attempt to address uniqueness of the bundle data itself and has no relation to concepts such as bundle fragmentation. Each invocation of TCPCL by the bundle protocol agent, requesting transmission of a bundle (fragmentary or otherwise), results in the initiation of a single TCPCL transfer. Each transfer entails the sending of a XFER\_INIT message and some number of XFER\_SEGMENT and XFER\_ACK messages; all are correlated by the same Transfer ID.

Transfer IDs from each node SHALL be unique within a single TCPCL session. The initial Transfer ID from each node SHALL have value zero. Subsequent Transfer ID values SHALL be incremented from the prior Transfer ID value by one. Upon exhaustion of the entire 64-bit Transfer ID space, the sending node SHALL terminate the session with SHUTDOWN reason code "Resource Exhaustion".

For bidirectional bundle transfers, a TCPCL node SHOULD NOT rely on any relation between Transfer IDs originating from each side of the TCPCL session.

### **5.3.2. Transfer Initialization (XFER\_INIT)**

The XFER\_INIT message contains the total length, in octets, of the bundle data in the associated transfer. The total length is formatted as a 64-bit unsigned integer.

The purpose of the XFER\_INIT message is to allow nodes to preemptively refuse bundles that would exceed their resources or to prepare storage on the receiving node for the upcoming bundle data. See [Section 5.3.5](#) for details on when refusal based on XFER\_INIT content is acceptable.

The Total Bundle Length field within a XFER\_INIT message SHALL be treated as authoritative by the receiver. If, for whatever reason, the actual total length of bundle data received differs from the value indicated by the XFER\_INIT message, the receiver SHOULD treat the transmitted data as invalid.

The format of the XFER\_INIT message is as follows:

```

+-----+
|      Message Header      |
+-----+
|   Transfer ID (U64)      |
+-----+
| Total bundle length (U64) |
+-----+

```

Figure 8: Format of XFER\_INIT Messages

The fields of the XFER\_INIT message are:

**Transfer ID:** A 64-bit unsigned integer identifying the transfer about to begin.

**Total bundle length:** A 64-bit unsigned integer indicating the size of the data-to-be-transferred.

An XFER\_INIT message SHALL be sent immediately before transmission of any XFER\_SEGMENT messages for each Transfer ID. XFER\_INIT messages MUST NOT be sent unless the next XFER\_SEGMENT message has the 'START' bit set to "1" (i.e., just before the start of a new transfer).

A receiver MAY send a BUNDLE\_REFUSE message as soon as it receives a XFER\_INIT message without waiting for the next XFER\_SEGMENT message. The sender MUST be prepared for this and MUST associate the refusal with the correct bundle via the Transfer ID fields.

### 5.3.3. Data Transmission (XFER\_SEGMENT)

Each bundle is transmitted in one or more data segments. The format of a XFER\_SEGMENT message follows in Figure 9.

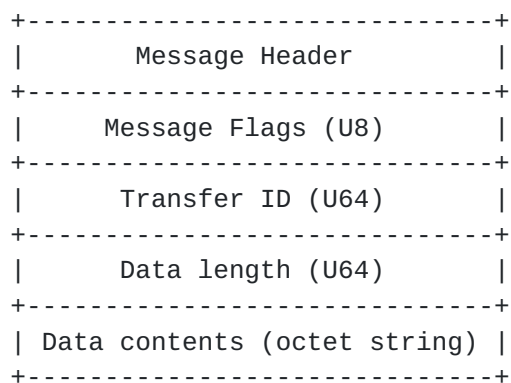

Figure 9: Format of XFER\_SEGMENT Messages

The fields of the XFER\_SEGMENT message are:

**Message Flags:** A one-octet field of single-bit flags, interpreted according to the descriptions in Table 5.

**Transfer ID:** A 64-bit unsigned integer identifying the transfer being made.

**Data length:** A 64-bit unsigned integer indicating the number of octets in the Data contents to follow.

**Data contents:** The variable-length data payload of the message.

Name	Code	Description
END	0x01	If bit is set, indicates that this is the last segment of the transfer.
START	0x02	If bit is set, indicates that this is the first segment of the transfer.
Reserved	others	

Table 5: XFER\_SEGMENT Flags

The flags portion of the message contains two optional values in the two low-order bits, denoted 'START' and 'END' in Table 5. The 'START' bit MUST be set to one if it precedes the transmission of the first segment of a transfer. The 'END' bit MUST be set to one when transmitting the last segment of a transfer. In the case where an entire transfer is accomplished in a single segment, both the 'START' and 'END' bits MUST be set to one.

Once a transfer of a bundle has commenced, the node MUST only send segments containing sequential portions of that bundle until it sends a segment with the 'END' bit set. No interleaving of multiple transfers from the same node is possible within a single TCPCL session. Simultaneous transfers between two nodes MAY be achieved using multiple TCPCL sessions.

#### [5.3.4.](#) Data Acknowledgments (XFER\_ACK)

Although the TCP transport provides reliable transfer of data between transport peers, the typical BSD sockets interface provides no means to inform a sending application of when the receiving application has processed some amount of transmitted data. Thus, after transmitting some data, a Bundle Protocol agent needs an additional mechanism to determine whether the receiving agent has successfully received the segment. To this end, the TCPCL protocol provides feedback messaging whereby a receiving node transmits acknowledgments of reception of data segments.

The format of an XFER\_ACK message follows in Figure 10.

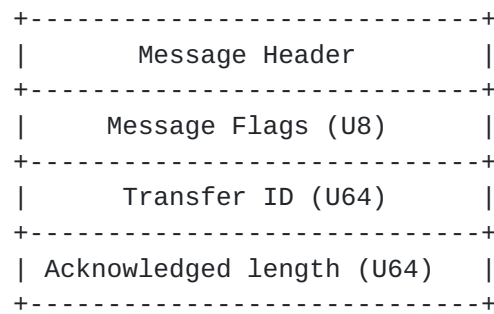

Figure 10: Format of XFER\_ACK Messages

The fields of the XFER\_ACK message are:

**Message Flags:** A one-octet field of single-bit flags, interpreted according to the descriptions in Table 5.

**Transfer ID:** A 64-bit unsigned integer identifying the transfer being acknowledged.

**Acknowledged length:** A 64-bit unsigned integer indicating the total number of octets in the transfer which are being acknowledged.

A receiving TCPCL endpoint SHALL send an XFER\_ACK message in response to each received XFER\_SEGMENT message. The flags portion of the XFER\_ACK header SHALL be set to match the corresponding DATA\_SEGMENT message being acknowledged. The acknowledged length of each XFER\_ACK contains the sum of the data length fields of all XFER\_SEGMENT messages received so far in the course of the indicated transfer.

For example, suppose the sending node transmits four segments of bundle data with lengths 100, 200, 500, and 1000, respectively. After receiving the first segment, the node sends an acknowledgment of length 100. After the second segment is received, the node sends an acknowledgment of length 300. The third and fourth acknowledgments are of length 800 and 1800, respectively.

#### 5.3.5. Transfer Refusal (XFER\_REFUSE)

The TCPCL supports a mechanism by which a receiving node can indicate to the sender that it does not want to receive the corresponding bundle. To do so, upon receiving a XFER\_INIT or XFER\_SEGMENT message, the node MAY transmit a XFER\_REFUSE message. As data segments and acknowledgments MAY cross on the wire, the bundle that is being refused SHALL be identified by the Transfer ID of the refusal.

There is no required relation between the Transfer MRU of a TCPCL node (which is supposed to represent a firm limitation of what the node will accept) and sending of a XFER\_REFUSE message. A XFER\_REFUSE can be used in cases where the agent's bundle storage is temporarily depleted or somehow constrained. A XFER\_REFUSE can also be used after the bundle header or any bundle data is inspected by an agent and determined to be unacceptable.

The format of the XFER\_REFUSE message is as follows:

```

+-----+
|      Message Header      |
+-----+
|      Reason Code (U8)    |
+-----+
|      Transfer ID (U64)   |
+-----+

```

Figure 11: Format of XFER\_REFUSE Messages

The fields of the XFER\_REFUSE message are:

**Reason Code:** A one-octet refusal reason code interpreted according to the descriptions in Table 6.

**Transfer ID:** A 64-bit unsigned integer identifying the transfer being refused.

Name	Semantics
Unknown	Reason for refusal is unknown or not specified.
Completed	The receiver already has the complete bundle. The sender MAY consider the bundle as completely received.
No Resources	The receiver's resources are exhausted. The sender SHOULD apply reactive bundle fragmentation before retrying.
Retransmit	The receiver has encountered a problem that requires the bundle to be retransmitted in its entirety.

Table 6: XFER\_REFUSE Reason Codes

The receiver **MUST**, for each transfer preceding the one to be refused, have either acknowledged all XFER\_SEGMENTs or refused the bundle transfer.

The bundle transfer refusal **MAY** be sent before an entire data segment is received. If a sender receives a XFER\_REFUSE message, the sender **MUST** complete the transmission of any partially sent XFER\_SEGMENT message. There is no way to interrupt an individual TCPCL message partway through sending it. The sender **MUST NOT** commence transmission of any further segments of the refused bundle subsequently. Note, however, that this requirement does not ensure that a node will not receive another XFER\_SEGMENT for the same bundle after transmitting a XFER\_REFUSE message since messages **MAY** cross on the wire; if this happens, subsequent segments of the bundle **SHOULD** also be refused with a XFER\_REFUSE message.

Note: If a bundle transmission is aborted in this way, the receiver **MAY** not receive a segment with the 'END' flag set to '1' for the aborted bundle. The beginning of the next bundle is identified by the 'START' bit set to '1', indicating the start of a new transfer, and with a distinct Transfer ID value.

## **6. Session Termination**

This section describes the procedures for ending a TCPCL session.

### **6.1. Shutdown Message (SHUTDOWN)**

To cleanly shut down a session, a SHUTDOWN message **MUST** be transmitted by either node at any point following complete transmission of any other message. After sending a SHUTDOWN message, the sender of the message **MAY** send further acknowledgments (XFER\_ACK or XFER\_REFUSE) but no further data messages (XFER\_INIT or XFER\_SEGMENT). A receiving node **SHOULD** acknowledge all received data segments before sending a SHUTDOWN message to end the session. A transmitting node **SHALL** treat a SHUTDOWN message received mid-transfer (i.e. before the final acknowledgment) as a failure of the transfer.

After transmitting a SHUTDOWN message, an node **MAY** immediately close the associated TCP connection. Once the SHUTDOWN message is sent, any further received data on the TCP connection **SHOULD** be ignored. Any delay between request to terminate the TCP connection and actual closing of the connection (a "half-closed" state) **MAY** be ignored by the TCPCL node.

The format of the SHUTDOWN message is as follows:

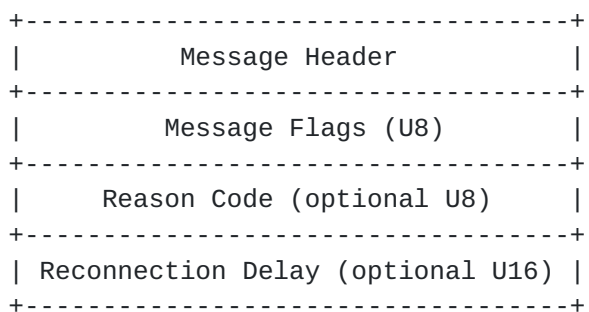

Figure 12: Format of SHUTDOWN Messages

The fields of the SHUTDOWN message are:

**Message Flags:** A one-octet field of single-bit flags, interpreted according to the descriptions in Table 7.

**Reason Code:** A one-octet refusal reason code interpreted according to the descriptions in Table 8. The Reason Code is present or absent as indicated by one of the flags.

**Reconnection Delay:** A 16-bit unsigned integer indicating the desired delay until further TCPCL sessions to the sending node. The Reconnection Delay is present or absent as indicated by one of the flags.

Name	Code	Description
D	0x01	If bit is set, indicates that a Reconnection Delay field is present.
R	0x02	If bit is set, indicates that a Reason Code field is present.
Reserved	others	

Table 7: SHUTDOWN Flags

It is possible for a node to convey additional information regarding the reason for session termination. To do so, the node **MUST** set the 'R' bit in the message flags and transmit a one-octet reason code immediately following the message header. The specified values of the reason code are:

Name	Description
Idle timeout	The session is being closed due to idleness.
Version mismatch	The node cannot conform to the specified TCPCL protocol version.
Busy	The node is too busy to handle the current session.
Contact Failure	The node cannot interpret or negotiate contact header option.
TLS Failure	The node failed to negotiate TLS session and cannot continue the session.
Resource Exhaustion	The node has run into some resource limit and cannot continue the session.

Table 8: SHUTDOWN Reason Codes

It is also possible to convey a requested reconnection delay to indicate how long the other node **MUST** wait before attempting session re-establishment. To do so, the node sets the 'D' bit in the message flags and then transmits an 16-bit unsigned integer specifying the requested delay, in seconds, following the message header (and optionally, the SHUTDOWN reason code). The value 0 **SHALL** be interpreted as an infinite delay, i.e., that the connecting node **MUST NOT** re-establish the session. In contrast, if the node does not wish to request a delay, it **SHOULD** omit the reconnection delay field (and set the 'D' bit to zero).

A session shutdown **MAY** occur immediately after TCP connection establishment or reception of a contact header (and prior to any further data exchange). This **MAY**, for example, be used to notify that the node is currently not able or willing to communicate. However, a node **MUST** always send the contact header to its peer before sending a SHUTDOWN message.

If either node terminates a session prematurely in this manner, it **SHOULD** send a SHUTDOWN message and **MUST** indicate a reason code unless the incoming connection did not include the magic string. If the magic string was not present, a node **SHOULD** close the TCP connection without sending a SHUTDOWN message. If a node does not want its peer to reopen a connection immediately, it **SHOULD** set the 'D' bit in the

flags and include a reconnection delay to indicate when the peer is allowed to attempt another session setup.

If a session is to be terminated before a protocol message has completed being sent, then the node **MUST NOT** transmit the SHUTDOWN message but still **SHOULD** close the TCP connection. Each TCPCL message is contiguous in the octet stream and has no ability to be cut short and/or preempted by an other message. This is particularly important when large segment sizes are being transmitted; either entire XFER\_SEGMENT is sent before a SHUTDOWN message or the connection is simply terminated mid-XFER\_SEGMENT.

## **6.2. Idle Session Shutdown**

The protocol includes a provision for clean shutdown of idle sessions. Determining the length of time to wait before closing idle sessions, if they are to be closed at all, is an implementation and configuration matter.

If there is a configured time to close idle links and if no TCPCL messages (other than KEEPALIVE messages) has been received for at least that amount of time, then either node **MAY** terminate the session by transmitting a SHUTDOWN message indicating the reason code of 'Idle timeout' (as described in Table 8).

## **7. Security Considerations**

One security consideration for this protocol relates to the fact that nodes present their endpoint identifier as part of the contact header exchange. It would be possible for a node to fake this value and present the identity of a singleton endpoint in which the node is not a member, essentially masquerading as another DTN node. If this identifier is used outside of a TLS-secured session or without further verification as a means to determine which bundles are transmitted over the session, then the node that has falsified its identity would be able to obtain bundles that it otherwise would not have. Therefore, a node **SHALL NOT** use the EID value of an unsecured contact header to derive a peer node's identity unless it can corroborate it via other means. When TCPCL session security mandated by a TCPCL peer, that peer **SHALL** transmit initial unsecured contact header values indicated in Table 9 in order. These values avoid unnecessarily leaking endpoint parameters and will be ignored when secure contact header re-exchange occurs.

Parameter	Value
Flags	The USE_TLS flag is set.
Keepalive Interval	Zero, indicating no keepalive.
Segment MRU	Zero, indicating all segments are refused.
Transfer MRU	Zero, indicating all transfers are refused.
EID	Empty, indicating lack of EID.

Table 9: Recommended Unsecured Contact Header

TCPCL can be used to provide point-to-point transport security, but does not provide security of data-at-rest and does not guarantee end-to-end bundle security. The mechanisms defined in [[RFC6257](#)] and [[I-D.ietf-dtn-bpsec](#)] are to be used instead.

Even when using TLS to secure the TCPCL session, the actual ciphersuite negotiated between the TLS peers MAY be insecure. TLS can be used to perform authentication without data confidentiality, for example. It is up to security policies within each TCPCL node to ensure that the negotiated TLS ciphersuite meets transport security requirements. This is identical behavior to STARTTLS use in [[RFC2595](#)].

Another consideration for this protocol relates to denial-of-service attacks. A node MAY send a large amount of data over a TCPCL session, requiring the receiving node to handle the data, attempt to stop the flood of data by sending a XFER\_REFUSE message, or forcibly terminate the session. This burden could cause denial of service on other, well-behaving sessions. There is also nothing to prevent a malicious node from continually establishing sessions and repeatedly trying to send copious amounts of bundle data. A listening node MAY take countermeasures such as ignoring TCP SYN messages, closing TCP connections as soon as they are established, waiting before sending the contact header, sending a SHUTDOWN message quickly or with a delay, etc.

## 8. IANA Considerations

In this section, registration procedures are as defined in [[RFC5226](#)].

Some of the registries below are created new for TCPCLv4 but share code values with TCPCLv3. This was done to disambiguate the use of

these values between TCPCLv3 and TCPCLv4 while preserving the semantics of some values.

### [8.1.](#) Port Number

Port number 4556 has been previously assigned as the default port for the TCP convergence layer in [[RFC7242](#)]. This assignment is unchanged by protocol version 4. Each TCPCL node identifies its TCPCL protocol version in its initial contact (see [Section 8.2](#)), so there is no ambiguity about what protocol is being used.

Parameter	Value
Service Name:	dtn-bundle
Transport Protocol(s):	TCP
Assignee:	Simon Perreault <simon@per.reau.lt>
Contact:	Simon Perreault <simon@per.reau.lt>
Description:	DTN Bundle TCP CL Protocol
Reference:	<a href="#">[RFC7242]</a>
Port Number:	4556

### [8.2.](#) Protocol Versions

IANA has created, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version Numbers" and initialized it with the following table. The registration procedure is RFC Required.

Value	Description	Reference
0	Reserved	[RFC7242]
1	Reserved	[RFC7242]
2	Reserved	[RFC7242]
3	TCPCL	[RFC7242]
4	TCPCLbis	This specification.
5-255	Unassigned	

### 8.3. Header Extension Types

EDITOR NOTE: sub-registry to-be-created upon publication of this specification.

IANA will create, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version 4 Header Extension Types" and initialized it with the contents of Table 10. The registration procedure is RFC Required within the lower range 0x0001--0x3fff. Values in the range 0x8000--0xffff are reserved for use on private networks for functions not published to the IANA.

Code	Message Type
0x0000	Reserved
0x0001--0x3fff	Unassigned
0x8000--0xffff	Private/Experimental Use

Table 10: Header Extension Type Codes

### 8.4. Message Types

EDITOR NOTE: sub-registry to-be-created upon publication of this specification.

IANA will create, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version 4

Message Types" and initialized it with the contents of Table 11. The registration procedure is RFC Required.

Code	Message Type
0x00	Reserved
0x01	XFER_SEGMENT
0x02	XFER_ACK
0x03	XFER_REFUSE
0x04	KEEPALIVE
0x05	SHUTDOWN
0x06	XFER_INIT
0x07	MSG_REJECT
0x08--0xf	Unassigned

Table 11: Message Type Codes

#### 8.5. XFER\_REFUSE Reason Codes

EDITOR NOTE: sub-registry to-be-created upon publication of this specification.

IANA will create, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version 4 XFER\_REFUSE Reason Codes" and initialized it with the contents of Table 12. The registration procedure is RFC Required.

Code	Refusal Reason
0x0	Unknown
0x1	Completed
0x2	No Resources
0x3	Retransmit
0x4--0x7	Unassigned
0x8--0xf	Reserved for future usage

Table 12: XFER\_REFUSE Reason Codes

#### 8.6. SHUTDOWN Reason Codes

EDITOR NOTE: sub-registry to-be-created upon publication of this specification.

IANA will create, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version 4 SHUTDOWN Reason Codes" and initialized it with the contents of Table 13. The registration procedure is RFC Required.

Code	Shutdown Reason
0x00	Idle timeout
0x01	Version mismatch
0x02	Busy
0x03	Contact Failure
0x04	TLS failure
0x05--0xFF	Unassigned

Table 13: SHUTDOWN Reason Codes

### 8.7. MSG\_REJECT Reason Codes

EDITOR NOTE: sub-registry to-be-created upon publication of this specification.

IANA will create, under the "Bundle Protocol" registry, a sub-registry titled "Bundle Protocol TCP Convergence-Layer Version 4 MSG\_REJECT Reason Codes" and initialized it with the contents of Table 14. The registration procedure is RFC Required.

Code	Rejection Reason
0x00	reserved
0x01	Message Type Unknown
0x02	Message Unsupported
0x03	Message Unexpected
0x04-0xFF	Unassigned

Table 14: REJECT Reason Codes

## 9. Acknowledgments

This memo is based on comments on implementation of [RFC7242] provided from Scott Burleigh.

#### **Appendix A.** Significant changes from [RFC7242](#)

The areas in which changes from [[RFC7242](#)] have been made to existing headers and messages are:

- o Changed contact header content to limit number of negotiated options.
- o Added contact option to negotiate maximum segment size (per each direction).
- o Added contact header extension capability.
- o Defined new IANA registries for message / type / reason codes to allow renaming some codes for clarity.
- o Expanded Message Header to octet-aligned fields instead of bit-packing.
- o Added a bundle transfer identification number to all bundle-related messages (XFER\_INIT, XFER\_SEGMENT, XFER\_ACK, XFER\_REFUSE).
- o Use flags in XFER\_ACK to mirror flags from XFER\_SEGMENT.
- o Removed all uses of SDNV fields and replaced with fixed-bit-length fields.

The areas in which extensions from [[RFC7242](#)] have been made as new messages and codes are:

- o Added contact negotiation failure SHUTDOWN reason code.
- o Added MSG\_REJECT message to indicate an unknown or unhandled message was received.
- o Added TLS session security mechanism.
- o Added TLS failure SHUTDOWN reason code.
