A LoST extension to return complete and similar location info

Abstract

This document introduces a new way to provide returned location information in LoST responses that is either of a completed or similar form to the original input civic location, based on whether valid or invalid civic address elements are returned within the <findServiceResponse> message. This document defines a new extension to the <findServiceResponse> message within the LoST protocol (RFC5222) that enables the LoST protocol to return in a response a completed civic address element set for a valid location response, and one or more suggested sets of similar location information for an invalid location. These two types of civic addresses are referred to as either "complete location" or "similar location", and are included as a compilation of CAtype xml elements within the existing LoST <findServiceResponse> message structure.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 15 July 2022.

1. Introduction

The LoST protocol [[RFC5222](#)] supports the validation of civic location information sent in a <findService> request, by providing a set of validation result status indicators in the response. The current usefulness of the supported xml elements <valid>, <invalid>, and <unchecked> is limited. They each provide an indication of validity for any one location element as a part of the whole civic address, but this is insufficient in providing either the complete set of civic address elements that the LoST server contains, or of providing alternate suggestions (hints) as to which civic address is intended for use.

Whether the queried civic location is valid but missing information, or invalid due to missing or wrong information, this document provides a mechanism to return a complete set of civic address elements.

This enhancement to the validation feature within LoST is required by systems that rely on accurate location for processing. Use of

this enhancement increases the likelihood that the correct and/or complete form of a civic location becomes known in those cases where it is incomplete or incorrect. One such use case is that of location-based emergency calling. The use of this protocol extension facilitates the timely correction of errors, and allows location servers to be more easily provisioned with complete address information.

The structure of this document includes terminology, [Section 2](#), followed by a discussion of the basic elements involved in location validation. The use of these elements, by way of example, is discussed in an overview section, [Section 3](#), with accompanying rationale, and a brief discussion of the impacts to LoST, and its current schema.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

The following terms are defined in this document:

Location: The term Location is in general used to refer to either a civic location or a geodetic location. In the context of this document, location is restricted to civic locations.

Geodetic Location: a geographic coordinate set of values that describes a point within a defined geographic datum. For example, a WGS84 referenced latitude, longitude coordinate pair (2D), or latitude, longitude, and altitude (3D). Note: geodetic location is defined here for context, but is not used elsewhere within this document.

Civic Location: The term Civic Location applies to a set of one or more Civic Address Elements that are used in conjunction with each other, and in accordance with a known ruleset to designate a specific place within a region of geography, or a region of geography by itself as defined in [[RFC5139](#)].

Civic Address: The term Civic Address is used interchangeably with the term Civic Location within this document.

Civic Address Element: The term Civic Address Element is used within this document to indicate any individual XML element used within the <civicAddress> type defined in [[RFC5139](#)], including elements used at the extension point therein such as those defined in [[RFC6848](#)] and elsewhere. This term also includes the reference to such elements by qualified name as defined within the <locationValidation> element in [[RFC5222](#)].

Invalid Location:

A Civic Location that, when included in a LoST query with 'validateLocation' set, will receive a response having one or more Civic Address Elements in the <invalid> list. Note that it is also possible that the location information submitted is so inaccurate that location validation cannot be performed, and the LoST server may return a <notFound> or <locationInvalid> error. In this document, the term Invalid Location only refers to a case where the LoST server returns one or more elements in the <invalid> list; the error conditions are not considered.

Valid Location: A Civic Location that, when included in a LoST query with 'validateLocation' set, will receive a response having all Civic Address Elements in the <valid> or <unchecked> lists.

Complete Location: An expanded civic location that includes other Civic Address Elements in addition to the existing validated Civic Address Elements provided as input to a LoST server. Complete Location may be returned when the input location is valid but incomplete

Similar Location: A suggested civic location that is similar to an Invalid Location which was used in a LoST query, but which has one or more elements added, modified, or removed such that the suggested location is a Valid Location. Similar Location may be returned when the input location is invalid

Returned Location Information: A set of civic locations returned in a LoST response.

3. Overview of Returned Location Information

This document describes an extension to LoST [[RFC5222](#)] that allows additional location information to be returned in the <locationValidation> element of a <findServiceResponse>. This extension is applicable when the location information in the <findService> request is in the Basic Civic profile as described in [[RFC5222](#)] or in another profile whose definition provides instructions concerning its use with this extension. As of this document's publication, no such additional location profiles have been defined, so this document describes the returned location extension using the Basic Civic profile. In addition, the following restriction is imposed: A server MUST NOT include Returned Location Information using a location profile that differs from the profile of the location used to answer the query and, by extension, MUST NOT include Returned Location Information using a location profile that was not used by the client in the request. This extension has two different use cases: First, when the input location is incomplete but the LoST server can identify the intended unique address, and

second, when the input location is invalid and the LoST server can identify one or more likely intended locations.

When a LoST server is asked to validate a civic location, its goal is to take the set of Civic Address Elements provided as the location information in the LoST request, and find a unique location in its database that matches the information in the request. Uniqueness might not require values for all possible elements in the Civic Address that the database might hold. Further, the input location information might not represent the form of location the users of the LoST service prefer to have. As an example, there are LoST Civic Address Elements that could be used to define a postal location, suitable for delivery of mail as well as a municipal location suitable for responding to an emergency call. While the LoST server might be able to determine the location from the postal elements provided, the emergency services would prefer that the municipal location be used for any subsequent emergency call. Since validation is often performed well in advance of an end-user placing an emergency call, if the LoST server could return the preferred form of location (or more properly in this example, the municipal elements in addition to the postal elements), those elements could be stored in a client application such as a Location Information Server (LIS) and used in a later emergency call.

In addition, this document describes the reuse of the same mechanism, but for a different purpose: to supply similar location information in the case where a LoST server response includes one or more Civic Address Elements marked as invalid, indicating an Invalid Location used in the query. In this case, the response contains one or more suggested alternative Valid Locations.

In a LoST <findServiceResponse> indicating a Valid Location i.e., containing the <locationValidation> element with no elements listed as invalid, the LoST server can use this extension to include additional location information in a <locationValidation> element. As an example, a query contains <HNO> (house number), <RD> (road name) <A3> (city), <A1> (state/province) but not <POD> (Post-Directional). In this example, there is no street with just the street name, all streets have a post-directional. However, the LoST server is able to uniquely locate the intended address and thus consider the queried location Valid, as there is only one street with the street name and house number in the city that it could be. As the queried location is missing the post-directional element, a more strict entity might consider it Invalid (e.g., during a subsequent query) or worse, the lack of a Post-Directional element might cause confusion and delay an emergency response. The server can use this extension to supply the missing post-directional element <POD> in a <completeLocation> element within the <locationValidation> element.

In another example, the civic location in a request might lack <A2> (county) and <PC> (Postal Code) Civic Address Elements. In this example, too, the LoST server is able uniquely locate the intended address and consider the location <Valid>, but other entities involved in a subsequent emergency call might find it helpful to have the additional Civic Address Elements. The LoST server can use this extension to supply the missing <A2> and <PC> Civic Address Elements.

Since [\[RFC5222\]](#) does not have a way for this additional location information to be returned in the <findServiceResponse>, this document extends the LoST protocol so that it can include a <completeLocation> element within the <locationValidation> element of the <findServiceResponse> message, allowing for the representation of complete location information.

An example showing complete location information supplied:

Input address:

6000 15th Avenue
Leets, WA US

Complete Location:

6000 15th Avenue Northwest
Leets, WA 98105 US

The information provided in the request may be enough to identify a unique location in the LoST server, but that may not be the location intended by the user. The <completeLocation> information may alert the user to a mismatch between the provided location information and the unique location the server interpreted that information to identify.

The other use case for this extension is when the <findService> request contains an Invalid Location. When a LoST server returns a response to a <findService> request that contains a set of Civic Address Elements with one or more listed as invalid, this extension allows the server to include in the <locationValidation> element one or more locations that might be the intended location.

In the example cited above, policy at the LoST server might deem a missing <A3> element as being invalid, even if the location information in the request is sufficient to identify a unique address. In this case, the missing element is listed in the <invalid> list, and a <similarLocation> element could be returned in the response showing a complete civic location that includes the missing <A3> element, just as in the above example the missing <A3> element is included in a <completeLocation> element.

As another example of the use of <similarLocation>, consider the results based on a similar data set as used above, but where the <HNO>, <RD>, <STS>, <A1>, and <A3> Civic Address Elements are not sufficient to locate a unique address, resulting in an invalid location response. Because the LoST server contains additional civic address elements which, had they been included in the query, would have resulted in a uniquely identifiable location, the server can include one or more <similarLocation> elements containing the supplied Civic Address Elements plus the omitted ones. Since [\[RFC5222\]](#) does not have a way for this additional location information to be returned in the <findServiceResponse>, this document extends [\[RFC5222\]](#) so that the LoST <locationValidation> element of the <findServiceResponse> can include one or more <similarLocation> elements representing similar civic locations.

To show this, suppose that a slightly modified version of the above address is sent within a Lost <findService> request:

Input address:

6000 15th Avenue North
Leets, WA US

This time we make the assumption that the address is deemed invalid by the LoST server because there is no such thing as "15th Avenue North" within the LoST server's data for the city of Leets. However, we also happen to know for this example that there are two addresses within the address dataset that are "similar", when all parts of the address are taken as a whole. These similar addresses that could be returned to the client are as follows:

Similar address #1:

6000 15th Avenue Northwest
Leets, WA 98107 US

Similar address #2:

6000 15th Avenue Northeast
Leets, WA 98105 US

This extension allows the LoST server to include the above similar addresses in the response to a <findService> request with 'validateLocaton' set to true. [Section 5](#) shows examples of the LoST request and response XML message fragments for the above valid and invalid scenarios, returning the complete or similar addresses respectively.

4. Returned Location Information

A LoST server implementing this extension MAY include `<completeLocation>` or `<similarLocation>` elements within the `<locationValidation>` portion of the `<findServiceResponse>`. The `<completeLocation>` and `<similarLocation>` elements are of type "locationInformation" as defined by the LoST schema in [\[RFC5222\]](#). These elements MAY contain location information either in the Basic Civic profile defined in RFC5222 or in another profile whose definition provides instructions concerning its use with this extension but this MUST be the same profile as the location in the query. When used with the Basic Civic profile, these elements contain a `<civicAddress>` element as defined in [\[RFC5139\]](#).

The LoST server MAY include more than one `<similarLocation>` element in the response. If there are too many possible locations, the server MAY return none, or it MAY return a subset considered most likely. How many to return is left to the implementation of the LoST server. The server is unable to know what the intended location information was supposed to be; it is guessing. Therefore the correct location may or may not be one of the `<similarLocation>` elements the server provides, and the client cannot assume that any one of them is the correct location.

Where a LoST server contains additional location information relating to the Civic Address used in a `<findService>` request, the `<findServiceResponse>` message MAY include a `<completeLocation>` element containing additional location information along with the original validated Civic Address Elements; the additional Civic Address Elements may be deemed by local policy as necessary to form a Complete Location. The `<completeLocation>` element MUST NOT be returned in response messages where any Civic Address Elements occur in the invalid list of the response, or where the set of Civic Address Elements in the request do not identify a unique location. The Complete Location MUST NOT contain any elements that would be marked as invalid, or cause an error, if a recipient of that location performs a subsequent `<findService>` request using the Complete Location. However, if a subsequent request includes the Complete Location, the corresponding response MAY include elements in the unchecked list.

Clients can control the return of additional location information by including the optional 'returnAdditionalLocation' attribute with possible values 'none', 'similar', 'complete' or 'any'. The value 'none' means to not return additional location information, 'similar' and 'complete' mean to only return the respective type of additional location information (if the server could send any) and 'any' means to include Similar and/or Complete Location (if the server could send any). If the request includes this attribute, the

server MUST NOT send location information contravening the client's request. Omitting this attribute in the request is equivalent to including it with the value 'none'.

The server may determine that there are many possible Similar Locations and decide not to send them all. The number of Similar Locations sent is entirely up to the server. The server MAY include a 'similarLocationsLimited' attribute which contains a non-zero integer indicating the minimum number of Similar Locations not included in the response. There may be more than the indicated similar locations available in the data held by the server.

Clients MAY ignore the location information this extension defines. The information is optional to send, and optional to use. In the case where the location information in the request was valid, this extension does not change the validity. In the case where the location information in the request is invalid, but alternate location information is returned, the original location remains invalid, and the LoST server does not change the mapping response other than optionally including the information defined by this extension.

The <completeLocation> and <similarLocation> elements use the <locationInformation> element from [RFC5222] updated by [I-D.ietf-ecrit-lost-planned-changes], including the 'profile' attribute, which is useful if the request contains location information in a profile other than the 'civic' profile. The 'profile' attribute MUST be included in both the request and the response and MUST be the same profile in both.

5. Examples

5.1. Complete Location returned for Valid Location

This example is based on the example request above; the LoST server considered the location in the query to be valid but missing some Civic Address elements, so in the Returned Location Information in the <findServiceResponse>, the server includes a <completeLocation> element supplying the omitted Civic Address elements <A2>, <PC>, and <PCN>.

      <xs:restriction base="xs:integer">
        <xs:minInclusive value="1"/>
      </xs:restriction>
    </xs:simpleType>
  </xs:attribute>

</xs:schema>

```

7. Security Considerations

Whether the input to the LoST server is a Valid or Invalid Location, the LoST server ultimately determines what it considers to be a Valid Location. Even in the case where the input location is valid, the requester still might not actually understand where that location is. For this kind of Valid Location use case, this extension will typically return more location information than what the requester started with, which might reveal to the requester additional information (additional CATypes) about the location. While this is very desirable in some scenarios such as supporting an emergency call, it might not be as desirable for other services. Individual LoST server implementations SHOULD consider the risk of releasing more detail versus the value in doing so. Generally, supplying more information (CATypes) is not considered to be a significant problem because the requester has to already have enough information for the location to be considered valid, which in most cases is enough to uniquely locate the address. Providing more CATypes generally doesn't actually reveal anything more. When Invalid Locations are submitted, this extension allows the LoST response to include locations that are similar to what was input, again resulting in more information provided in the response than was sent in the request. LoST server implementations SHOULD evaluate the particular use cases where this extension is supported, and weigh the risks around its use. Many services available today via the Internet offer similar features, such as "did you mean" or address completion, so this capability is not introducing any fundamentally new threat.

8. IANA Considerations

8.1. XML Schema Registration

URI: urn:ietf:params:xml:schema:lost-rli1

Registrant Contact: IETF ECRIT Working Group, Brian Rosen
(br@brianrosen.net).

XML Schema: The XML schema to be registered is contained
in <xref target="XMLSchema"/>.

8.2. LoST-RLI Namespace Registration

URI: urn:ietf:params:xml:ns:lost-rli1

Registrant Contact: IETF ECRIT Working Group, Brian Rosen
(br@brianrosen.net).

XML:

```
