Host Identity Protocol (HIP) Rendezvous Extension
draft-ietf-hip-rfc5204-bis-00

Abstract

This document defines a rendezvous extension for the Host Identity Protocol (HIP). The rendezvous extension extends HIP and the HIP registration extension for initiating communication between HIP nodes via HIP rendezvous servers. Rendezvous servers improve reachability and operation when HIP nodes are multi-homed or mobile.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on February 21, 2011.

1. Introduction

The Host Identity Protocol (HIP) Architecture [[RFC4423](#)] introduces the rendezvous mechanism to help a HIP node to contact a frequently moving HIP node. The rendezvous mechanism involves a third party, the rendezvous server (RVS), which serves as an initial contact point ("rendezvous point") for its clients. The clients of an RVS are HIP nodes that use the HIP Registration Extension [[RFC5203](#)] to register their HIT->IP address mappings with the RVS. After this registration, other HIP nodes can initiate a base exchange using the IP address of the RVS instead of the current IP address of the node they attempt to contact. Essentially, the clients of an RVS become reachable at the RVS's IP address. Peers can initiate a HIP base exchange with the IP address of the RVS, which will relay this initial communication such that the base exchange may successfully complete.

2. Terminology

This section defines terms used throughout the remainder of this specification.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

In addition to the terminology defined in the HIP specification [[RFC5201](#)] and the HIP Registration Extension [[RFC5203](#)], this document defines and uses the following terms:

Rendezvous Service

A HIP service provided by a rendezvous server to its rendezvous clients. The rendezvous server offers to relay some of the arriving base exchange packets between the initiator and responder.

Rendezvous Server (RVS)

A HIP registrar providing rendezvous service.

Rendezvous Client

A HIP requester that has registered for rendezvous service at a rendezvous server.

Rendezvous Registration

A HIP registration for rendezvous service, established between a rendezvous server and a rendezvous client.

3. Overview of Rendezvous Server Operation

Figure 1 shows a simple HIP base exchange without a rendezvous server, in which the initiator initiates the exchange directly with the responder by sending an I1 packet to the responder's IP address, as per the HIP specification [[RFC5201](#)].

Figure 1: HIP base exchange without rendezvous server.

The End-Host Mobility and Multihoming with the Host Identity Protocol specification [[RFC5206](#)] allows a HIP node to notify its peers about changes in its set of IP addresses. This specification presumes initial reachability of the two nodes with respect to each other.

However, such a HIP node MAY also want to be reachable to other future correspondent peers that are unaware of its location change. The HIP Architecture [[RFC4423](#)] introduces rendezvous servers with whom a HIP node MAY register its host identity tags (HITs) and current IP addresses. An RVS relays HIP packets arriving for these HITs to the node's registered IP addresses. When a HIP node has registered with an RVS, it SHOULD record the IP address of its RVS in its DNS record, using the HIP DNS resource record type defined in the HIP DNS Extension [[RFC5205](#)].

Figure 2: HIP base exchange with a rendezvous server.

Figure 2 shows a HIP base exchange involving a rendezvous server. It is assumed that HIP node R previously registered its HITs and current IP addresses with the RVS, using the HIP Registration Extension [[RFC5203](#)]. When the initiator I tries to establish contact with the

responder R, it must send the I1 of the base exchange either to one of R's IP addresses (if known via DNS or other means) or to one of R's rendezvous servers. Here, I obtains the IP address of R's rendezvous server from R's DNS record and then sends the I1 packet of the HIP base exchange to RVS. RVS, noticing that the HIT contained in the arriving I1 packet is not one of its own, MUST check its current registrations to determine if it needs to relay the packets. Here, it determines that the HIT belongs to R and then relays the I1 packet to the registered IP address. R then completes the base exchange without further assistance from RVS by sending an R1 directly to the I's IP address, as obtained from the I1 packet. In this specification, the client of the RVS is always the responder. However, there might be reasons to allow a client to initiate a base exchange through its own RVS, like NAT and firewall traversal. This specification does not address such scenarios, which should be specified in other documents.

3.1. Diagram Notation

Notation -----	Significance -----
I, R	I and R are the respective source and destination IP addresses in the IP header.
HIT-I, HIT-R	HIT-I and HIT-R are the initiator's and the responder's HITs in the packet, respectively.
REG_REQ	A REG_REQUEST parameter is present in the HIP header.
REG_RES	A REG_RESPONSE parameter is present in the HIP header.
FROM:I	A FROM parameter containing the IP address I is present in the HIP header.
RVS_HMAC	An RVS_HMAC parameter containing an HMAC keyed with the appropriate registration key is present in the HIP header.
VIA:RVS	A VIA_RVS parameter containing the IP address RVS of a rendezvous server is present in the HIP header.

3.2. Rendezvous Client Registration

Before a rendezvous server starts to relay HIP packets to a rendezvous client, the rendezvous client needs to register with it to receive rendezvous service by using the HIP Registration Extension [[RFC5203](#)] as illustrated in the following schema:

Rendezvous client registering with a rendezvous server.

3.3. Relaying the Base Exchange

If a HIP node and one of its rendezvous servers have a rendezvous registration, the rendezvous servers relay inbound I1 packets (that contain one of the client's HITs) by rewriting the IP header. They replace the destination IP address of the I1 packet with one of the IP addresses of the owner of the HIT, i.e., the rendezvous client. They MUST also recompute the IP checksum accordingly.

Because of egress filtering on the path from the RVS to the client [RFC2827][RFC3013], a HIP rendezvous server SHOULD replace the source IP address, i.e., the IP address of I, with one of its own IP addresses. The replacement IP address SHOULD be chosen according to relevant IPv4 and IPv6 specifications [RFC1122][RFC3484]. Because this replacement conceals the initiator's IP address, the RVS MUST append a FROM parameter containing the original source IP address of the packet. This FROM parameter MUST be integrity protected by an RVS_HMAC keyed with the corresponding rendezvous registration integrity key [RFC5203].

This specification defines an additional registration for the HIP Registration Extension [RFC5203] that allows registering with a rendezvous server for rendezvous service.

Number	Registration Type
-----	-----
1	RENDEZVOUS

4.2. Parameter Formats and Processing

4.2.1. RVS_HMAC Parameter

The RVS_HMAC is a non-critical parameter whose only difference with the HMAC parameter defined in the HIP specification [[RFC5201](#)] is its "type" code. This change causes it to be located after the FROM parameter (as opposed to the HMAC):

Type	65500
Length	Variable. Length in octets, excluding Type, Length, and Padding.
HMAC	HMAC computed over the HIP packet, excluding the RVS_HMAC parameter and any following parameters. The HMAC is keyed with the appropriate HIP integrity key (HIP-lg or HIP-gl) established when rendezvous registration happened. The HIP "checksum" field MUST be set to zero, and the HIP header length in the HIP common header MUST be calculated not to cover any excluded parameter when the HMAC is calculated. The size of the HMAC is the natural size of the hash computation output depending on the used hash function.

To allow a rendezvous client and its RVS to verify the integrity of packets flowing between them, both SHOULD protect packets with an added RVS_HMAC parameter keyed with the HIP-lg or HIP-gl integrity key established while registration occurred. A valid RVS_HMAC SHOULD be present on every packet flowing between a client and a server and MUST be present when a FROM parameter is processed.

An initiator SHOULD NOT send an opportunistic I1 with a NULL destination HIT to an IP address that is known to be a rendezvous server address, unless it wants to establish a HIP association with the rendezvous server itself and does not know its HIT.

When an RVS rewrites the source IP address of an I1 packet due to egress filtering, it MUST add a FROM parameter to the I1 that contains the initiator's source IP address. This FROM parameter MUST be protected by an RVS_HMAC keyed with the integrity key established at rendezvous registration.

4.3.2. Processing Incoming I1 Packets

When a rendezvous server receives an I1 whose destination HIT is not its own, it consults its registration database to find a registration for the rendezvous service established by the HIT owner. If it finds an appropriate registration, it relays the packet to the registered IP address. If it does not find an appropriate registration, it drops the packet.

A rendezvous server SHOULD interpret any incoming opportunistic I1 (i.e., an I1 with a NULL destination HIT) as an I1 addressed to itself and SHOULD NOT attempt to relay it to one of its clients.

When a rendezvous client receives an I1, it MUST validate any present RVS_HMAC parameter. If the RVS_HMAC cannot be verified, the packet SHOULD be dropped. If the RVS_HMAC cannot be verified and a FROM parameter is present, the packet MUST be dropped.

A rendezvous client acting as responder SHOULD drop opportunistic I1s that include a FROM parameter, because this indicates that the I1 has been relayed.

4.3.3. Processing Outgoing R1 Packets

When a responder replies to an I1 relayed via an RVS, it MUST append to the regular R1 header a VIA_RVS parameter containing the IP addresses of the traversed RVSs.

4.3.4. Processing Incoming R1 Packets

The HIP specification [[RFC5201](#)] mandates that a system receiving an R1 MUST first check to see if it has sent an I1 to the originator of the R1 (i.e., the system is in state I1-SENT). When the R1 is replying to a relayed I1, this check SHOULD be based on HITs only. In case the IP addresses are also checked, then the source IP address MUST be checked against the IP address included in the VIA_RVS parameter.

5. Security Considerations

This section discusses the known threats introduced by these HIP extensions and the implications on the overall security of HIP. In particular, it argues that the extensions described in this document do not introduce additional threats to the Host Identity Protocol.

It is difficult to encompass the whole scope of threats introduced by rendezvous servers because their presence has implications both at the IP and HIP layers. In particular, these extensions might allow for redirection, amplification, and reflection attacks at the IP layer, as well as attacks on the HIP layer itself, for example, man-in-the-middle attacks against the HIP base exchange.

If an initiator has a priori knowledge of the responder's host identity when it first contacts the responder via an RVS, it has a means to verify the signatures in the HIP base exchange, which protects against man-in-the-middle attacks.

If an initiator does not have a priori knowledge of the responder's host identity (so-called "opportunistic initiators"), it is almost impossible to defend the HIP exchange against these attacks, because the public keys exchanged cannot be authenticated. The only approach would be to mitigate hijacking threats on HIP state by requiring an R1 answering an opportunistic I1 to come from the same IP address that originally sent the I1. This procedure retains a level of security that is equivalent to what exists in the Internet today.

However, for reasons of simplicity, this specification does not allow the establishment of a HIP association via a rendezvous server in an opportunistic manner.

6. IANA Considerations

This section is to be interpreted according to the Guidelines for Writing an IANA Considerations Section in RFCs [[RFC2434](#)].

This document updates the IANA Registry for HIP Parameters Types by assigning new HIP Parameter Types values for the new HIP Parameters defined in [Section 4.2](#):

- o RVS_HMAC (defined in [Section 4.2.1](#))
- o FROM (defined in [Section 4.2.2](#))
- o VIA_RVS (defined in [Section 4.2.3](#))

This document defines an additional registration for the HIP Registration Extension [[RFC5203](#)] that allows registering with a rendezvous server for rendezvous service.

Number	Registration Type
-----	-----
1	RENDEZVOUS
