HTTP Alternative Services
draft-ietf-httpbis-alt-svc-00

Abstract

This document specifies "alternative services" for HTTP, which allow an origin's resources to be authoritatively available at a separate network location, possibly accessed with a different protocol configuration.

Editorial Note (To be removed by RFC Editor)

Discussion of this draft takes place on the HTTPBIS working group mailing list (ietf-http-wg@w3.org), which is archived at <http://lists.w3.org/Archives/Public/ietf-http-wg/>.

Working Group information can be found at <http://tools.ietf.org/wg/httpbis/>; that specific to HTTP/2 are at <http://http2.github.io/>.

The changes in this draft are summarized in [Appendix A](#).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 29, 2014.

1. Introduction

HTTP [[HTTP-p1](#)] conflates the identification of resources with their location. In other words, "http://" (and "https://") URLs are used to both name and find things to interact with.

In some cases, it is desirable to separate these aspects; to be able to keep the same identifier for a resource, but interact with it using a different location on the network.

For example:

- o An origin server might wish to redirect a client to an alternative when it needs to go down for maintenance, or it has found an alternative in a location that is more local to the client.
- o An origin server might wish to offer access to its resources using a new protocol (such as HTTP/2, see [[HTTP2](#)]) or one using improved security (such as TLS, see [[RFC5246](#)]).
- o An origin server might wish to segment its clients into groups of capabilities, such as those supporting Server Name Indication (SNI, see [Section 3 of \[RFC6066\]](#)) and those not supporting it, for operational purposes.

This specification defines a new concept in HTTP, "Alternative Services", that allows a resource to nominate additional means of interacting with it on the network. It defines a general framework for this in [Section 2](#), along with a specific mechanism for discovering them using HTTP header fields in [Section 3](#).

It also introduces a new status code in [Section 5](#), so that origin servers (or their nominated alternatives) can indicate that they are not authoritative for a given origin, in cases where the wrong location is used.

1.1. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

This document uses the Augmented BNF defined in [[RFC5234](#)] along with the "OWS", "DIGIT", "DQUOTE", "parameter", "uri-host", "port" and "delta-second" rules from [[HTTP-p1](#)], and uses the "#rule" extension defined in [Section 7](#) of that document.

2. Alternative Services Concepts

This specification defines a new concept in HTTP, the "alternative service". When an origin (see [[RFC6454](#)]) has resources that are accessible through a different protocol / host / port combination, it is said to have an alternative service.

An alternative service can be used to interact with the resources on an origin server at a separate location on the network, possibly using a different protocol configuration. Alternative services are considered authoritative for an origin's resources, in the sense of [[HTTP-p1](#)], Section 9.1.

For example, an origin:

```
("http", "www.example.com", "80")
```

might declare that its resources are also accessible at the alternative service:

```
("h2", "new.example.com", "81")
```

By their nature, alternative services are explicitly at the granularity of an origin; i.e., they cannot be selectively applied to resources within an origin.

Alternative services do not replace or change the origin for any given resource; in general, they are not visible to the software "above" the access mechanism. The alternative service is essentially

alternative routing information that can also be used to reach the origin in the same way that DNS CNAME or SRV records define routing information at the name resolution level. Each origin maps to a set of these routes - the default route is derived from origin itself and the other routes are introduced based on alternative-protocol information.

Furthermore, it is important to note that the first member of an alternative service tuple is different from the "scheme" component of an origin; it is more specific, identifying not only the major version of the protocol being used, but potentially communication options for that protocol.

This means that clients using an alternative service will change the host, port and protocol that they are using to fetch resources, but these changes MUST NOT be propagated to the application that is using HTTP; from that standpoint, the URI being accessed and all information derived from it (scheme, host, port) are the same as before.

Importantly, this includes its security context; in particular, when TLS [[RFC5246](#)] is in use, the alternative server will need to present a certificate for the origin's host name, not that of the alternative. Likewise, the Host header field is still derived from the origin, not the alternative service (just as it would if a CNAME were being used).

The changes MAY, however, be made visible in debugging tools, consoles, etc.

Formally, an alternative service is identified by the combination of:

- o An ALPN protocol, as per [[I-D.ietf-tls-applayerprotoneg](#)]
- o A host, as per [[RFC3986](#)]
- o A port, as per [[RFC3986](#)]

Additionally, each alternative service MUST have:

- o A freshness lifetime, expressed in seconds; see [Section 2.2](#)

There are many ways that a client could discover the alternative service(s) associated with an origin.

[2.1.](#) Host Authentication

Clients MUST NOT use alternative services with a host other than the origin's without strong server authentication; this mitigates the attack described in [Section 7.2](#). One way to achieve this is for the alternative to use TLS with a certificate that is valid for that origin.

For example, if the origin's host is "www.example.com" and an alternative is offered on "other.example.com" with the "h2" protocol, and the certificate offered is valid for "www.example.com", the client can use the alternative. However, if "other.example.com" is offered with the "h2c" protocol, the client cannot use it, because there is no mechanism in that protocol to establish strong server authentication.

Furthermore, this means that the HTTP Host header field and the SNI information provided in TLS by the client will be that of the origin, not the alternative.

[2.2.](#) Alternative Service Caching

Mechanisms for discovering alternative services can associate a freshness lifetime with them; for example, the Alt-Svc header field uses the "ma" parameter.

Clients MAY choose to use an alternative service instead of the origin at any time when it is considered fresh; see [Section 2.4](#) for specific recommendations.

Clients with existing connections to alternative services are not required to fall back to the origin when its freshness lifetime ends; i.e., the caching mechanism is intended for limiting how long an alternative service can be used for establishing new requests, not limiting the use of existing ones.

To mitigate risks associated with caching compromised values (see [Section 7.2](#) for details), user agents SHOULD examine cached alternative services when they detect a change in network configuration, and remove any that could be compromised (for example, those whose association with the trust root is questionable). UAs that do not have a means of detecting network changes SHOULD place an upper bound on their lifetime.

[2.3.](#) Requiring Server Name Indication

A client must only use a TLS-based alternative service if the client also supports TLS Server Name Indication (SNI) ([\[RFC6066\]](#), [Section 3](#)). This supports the conservation of IP addresses on the alternative service host.

[2.4.](#) Using Alternative Services

By their nature, alternative services are optional; clients are not required to use them. However, it is advantageous for clients to behave in a predictable way when they are used by servers (e.g., for load balancing).

Therefore, if a client becomes aware of an alternative service, the client SHOULD use that alternative service for all requests to the associated origin as soon as it is available, provided that the security properties of the alternative service protocol are desirable, as compared to the existing connection.

When a client uses an alternate service, it MUST emit the Service header field ([Section 4](#)) on every request using that alternate service.

The client is not required to block requests; the origin's connection can be used until the alternative connection is established. However, if the security properties of the existing connection are weak (e.g. cleartext HTTP/1.1) then it might make sense to block until the new connection is fully available in order to avoid information leakage.

Furthermore, if the connection to the alternative service fails or is

unresponsive, the client MAY fall back to using the origin. Note, however, that this could be the basis of a downgrade attack, thus losing any enhanced security properties of the alternative service.

3. The Alt-Svc HTTP Header Field

An HTTP(S) origin server can advertise the availability of alternative services (see [Section 2](#)) to clients by adding an Alt-Svc header field to responses.

```
Alt-Svc      = 1#( alternative *( OWS ";" OWS parameter ) )
alternative = DQUOTE protocol-id DQUOTE "=" port
protocol-id  = <ALPN protocol identifier>
```

For example:

```
Alt-Svc: "http2"=8000
```

This indicates that the "http2" protocol on the same host using the indicated port (in this case, 8000).

Alt-Svc MAY occur in any HTTP response message, regardless of the status code.

Alt-Svc does not allow advertisement of alternative services on other hosts, to protect against various header-based attacks.

It can, however, have multiple values:

```
Alt-Svc: "h2c"=8000, "h2"=443
```

The value(s) advertised by Alt-Svc can be used by clients to open a new connection to one or more alternative services immediately, or simultaneously with subsequent requests on the same connection.

Intermediaries MUST NOT change or append Alt-Svc values.

Finally, note that while it may be technically possible to put content other than printable ASCII in a HTTP header field, some implementations only support ASCII (or a superset of it) in header

field values. Therefore, this field SHOULD NOT be used to convey

protocol identifiers that are not printable ASCII, or those that contain quote characters.

[[syntax: The header field syntax is both misleading (use of double quotes although not a quoted string) and incomplete (does not support all values). Alternate proposal in <<http://lists.w3.org/Archives/Public/ietf-http-wg/2014JanMar/0856.html>>.]]

3.1. Caching Alt-Svc Header Field Values

When an alternative service is advertised using Alt-Svc, it is considered fresh for 24 hours from generation of the message. This can be modified with the 'ma' (max-age) parameter;

```
Alt-Svc: "h2"=443;ma=3600
```

which indicates the number of seconds since the response was generated the alternative service is considered fresh for.

ma = delta-seconds

See Section 4.2.3 of [[HTTP-p6](#)] for details of determining response age.

For example, a response:

```
HTTP/1.1 200 OK
Content-Type: text/html
Cache-Control: 600
Age: 30
Alt-Svc: "h2c"=8000; ma=60
```

indicates that an alternative service is available and usable for the next 60 seconds. However, the response has already been cached for 30 seconds (as per the Age header field value), so therefore the alternative service is only fresh for the 30 seconds from when this response was received, minus estimated transit time.

When an Alt-Svc response header field is received from an origin, its value invalidates and replaces all cached alternative services for that origin.

See [Section 2.2](#) for general requirements on caching alternative services.

Note that the freshness lifetime for HTTP caching (here, 600 seconds) does not affect caching of Alt-Svc values.

4. The Service HTTP Header Field

The Service HTTP header field is used in requests to indicate the identity of the alternate service in use, just as the Host header field identifies the host and port of the origin.

```
Service = uri-host [ ":" port ]
```

Service is intended to allow alternate services to detect loops, differentiate traffic for purposes of load balancing, and generally to ensure that it is possible to identify the intended destination of traffic, since introducing this information after a protocol is in use has proven to be problematic.

When using an Alternate Service, clients **MUST** include a Service header in all requests.

For example:

```
GET /thing
Host: origin.example.com
Service: alternate.example.net
User-Agent: Example/1.0
```

5. The 4NN Not Authoritative HTTP Status Code

The 4NN (Not Authoritative) status code indicates that the current origin server (usually, but not always an alternative service; see [Section 2](#)) is not authoritative for the requested resource, in the sense of [[HTTP-p1](#)], Section 9.1.

Clients receiving 4NN (Not Authoritative) from an alternative service **MUST** remove the corresponding entry from its alternative service cache (see [Section 2.2](#)) for that origin. Regardless of the idempotency of the request method, they **MAY** retry the request, either at another alternative server, or at the origin.

4NN (Not Authoritative) **MAY** carry an Alt-Svc header field.

This status code **MUST NOT** be generated by proxies.

A 4NN response is cacheable by default; i.e., unless otherwise indicated by the method definition or explicit cache controls (see Section 4.2.2 of [[HTTP-p6](#)]).

[[code: We should decide on the status code before Last Call.]]

Alternative Services

March 2014

[7.](#) Security Considerations

Identified security considerations should be enumerated in the appropriate documents depending on which proposals are accepted. Those listed below are generic to all uses of alternative services; more specific ones might be necessary.

[7.1.](#) Changing Ports

Using an alternative service implies accessing an origin's resources on an alternative port, at a minimum. An attacker that can inject alternative services and listen at the advertised port is therefore able to hijack an origin.

For example, an attacker that can add HTTP response header fields can redirect traffic to a different port on the same host using the Alt-Svc header field; if that port is under the attacker's control, they can thus masquerade as the HTTP server.

This risk can be mitigated by restricting the ability to advertise alternative services, and restricting who can open a port for listening on that host.

[7.2.](#) Changing Hosts

When the host is changed due to the use of an alternative service, it presents an opportunity for attackers to hijack communication to an origin.

For example, if an attacker can convince a user agent to send all traffic for "innocent.example.org" to "evil.example.com" by successfully associating it as an alternative service, they can

masquerade as that origin. This can be done locally (see mitigations above) or remotely (e.g., by an intermediary as a man-in-the-middle attack).

This is the reason for the requirement in [Section 2.1](#) that any alternative service with a host different to the origin's be strongly authenticated with the origin's identity; i.e., presenting a certificate for the origin proves that the alternative service is authorized to serve traffic for the origin.

However, this authorization is only as strong as the method used to authenticate the alternative service. In particular, there are well-known exploits to make an attacker's certificate appear as legitimate.

Alternative services could be used to persist such an attack; for

example, an intermediary could man-in-the-middle TLS-protected communication to a target, and then direct all traffic to an alternative service with a large freshness lifetime, so that the user agent still directs traffic to the attacker even when not using the intermediary.

As a result, there is a requirement in [Section 2.2](#) to examine cached alternative services when a network change is detected.

[7.3.](#) Changing Protocols

When the ALPN protocol is changed due to the use of an alternative service, the security properties of the new connection to the origin can be different from that of the "normal" connection to the origin, because the protocol identifier itself implies this.

For example, if a "https://" URI had a protocol advertised that does not use some form of end-to-end encryption (most likely, TLS), it violates the expectations for security that the URI scheme implies.

Therefore, clients cannot blindly use alternative services, but instead evaluate the option(s) presented to assure that security requirements and expectations (of specifications, implementations and end users) are met.

[8.](#) Acknowledgements

Thanks to Eliot Lear, Stephen Farrell, Guy Podjarny, Stephen Ludin, Erik Nygren, Paul Hoffman, Adam Langley, Will Chan and Richard Barnes for their feedback and suggestions.

The Alt-Svc header field was influenced by the design of the Alternative-Protocol header field in SPDY.
