Software-Defined Networking (SDN)-based IPsec Flow Protection draft-ietf-i2nsf-sdn-ipsec-flow-protection-12

Abstract

This document describes how to provide IPsec-based flow protection (integrity and confidentiality) by means of an Interface to Network Security Function (I2NSF) controller. It considers two main wellknown scenarios in IPsec: (i) gateway-to-gateway and (ii) host-tohost. The service described in this document allows the configuration and monitoring of IPsec Security Associations (SAs) from a I2NSF Controller to one or several flow-based Network Security Functions (NSFs) that rely on IPsec to protect data traffic.

The document focuses on the I2NSF NSF-facing interface by providing YANG data models for configuring the IPsec databases (SPD, SAD, PAD) and IKEv2. This allows IPsec SA establishment with minimal intervention by the network administrator. It does not define any new protocol.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 3, 2021.

1. Introduction

Software-Defined Networking (SDN) is an architecture that enables users to directly program, orchestrate, control and manage network resources through software. The SDN paradigm relocates the control of network resources to a centralized entity, namely SDN Controller. SDN controllers configure and manage distributed network resources and provide an abstracted view of the network resources to SDN applications. SDN applications can customize and automate the operations (including management) of the abstracted network resources in a programmable manner via this interface [RFC7149] [ITU-T.Y.3300] [ONF-SDN-Architecture] [ONF-OpenFlow].

Recently, several network scenarios now demand a centralized way of managing different security aspects. For example, Software-Defined WANs (SD-WANs). SD-WANs are an SDN extension providing a software abstraction to create secure network overlays over traditional WAN and branch networks. SD-WANs utilize IPsec [RFC4301] as an underlying security protocol. The goal of SD-WANs is to provide flexible and automated deployment from a centralized point to enable on-demand network security services such as IPsec Security Association (IPsec SA) management. Additionally, Section 4.3.3 in [RFC8192] describes another example use case for Cloud Data Center Scenario titled "Client-Specific Security Policy in Cloud VPNs". The use case in RFC 8192 states that "dynamic key management is critical for securing the VPN and the distribution of policies". These VPNs can be established using IPsec. The management of IPsec SAs in data centers using a centralized entity is a scenario where the current specification maybe applicable.

Therefore, with the growth of SDN-based scenarios where network resources are deployed in an autonomous manner, a mechanism to manage IPsec SAs from a centralized entity becomes more relevant in the industry.

In response to this need, the Interface to Network Security Functions (I2NSF) charter states that the goal of this working group is "to define set of software interfaces and data models for controlling and monitoring aspects of physical and virtual Network Security Functions". As defined in [RFC8192] an NSF is "a function that is

Internet-Draft

used to ensure integrity, confidentiality, or availability of network communication; to detect unwanted network activity; or to block, or at least mitigate, the effects of unwanted activity". This document pays special attention to flow-based NSFs that ensure integrity and confidentiality by means of IPsec.

In fact, as Section 3.1.9 in [RFC8192] states "there is a need for a controller to create, manage, and distribute various keys to distributed NSFs.", however "there is a lack of a standard interface to provision and manage security associations". Inspired in the SDN paradigm, the I2NSF framework [RFC8329] defines a centralized entity, the I2NSF Controller, which manages one or multiple NSFs through a I2NSF NSF-Facing interface. In this document we define a service allowing the I2NSF Controller to carry out the key management procedures. More specifically, we define YANG data models for I2NSF NSF-Facing interface that allow the I2NSF Controller to configure and monitor IPsec-enabled flow-based NSFs.

IPsec architecture [RFC4301] defines clear separation between the processing to provide security services to IP packets and the key management procedures to establish the IPsec Security Associations, which allows to centralize the key management procedures in the I2NSF Controller. This document considers two typical scenarios to autonomously manage IPsec SAs: gateway-to-gateway and host-to-host [RFC6071]. In these cases, hosts, gateways or both may act as NSFs. Consideration for the host-to-gateway scenario is out of scope.

For the definition of the YANG data model for I2NSF NSF-Facing interface, this document considers two general cases, namely:

- 1) IKE case. The NSF implements the Internet Key Exchange version 2 (IKEv2) protocol and the IPsec databases: the Security Policy Database (SPD), the Security Association Database (SAD) and the Peer Authorization Database (PAD). The I2NSF Controller is in charge of provisioning the NSF with the required information in the SPD, PAD (e.g. IKE credential) and IKE protocol itself (e.g. parameters for the IKE_SA_INIT negotiation).
- 2) IKE-less case. The NSF only implements the IPsec databases (no IKE implementation). The I2NSF Controller will provide the required parameters to create valid entries in the SPD and the SAD into the NSF. Therefore, the NSF will have only support for IPsec while key management functionality is moved to the I2NSF Controller.

In both cases, a data model for the I2NSF NSF-Facing interface is required to carry out this provisioning in a secure manner between the I2NSF Controller and the NSF. Using YANG data modelling language version 1.1 [RFC7950] and based on YANG models defined in [netconf-vpn], [I-D.tran-ipsecme-yang], RFC 4301 [RFC4301] and RFC 7296 [RFC7296], this document defines the required interfaces with a YANG model for configuration and state data for IKE, PAD, SPD and SAD (see Appendix A, Appendix B and Appendix C). The proposed YANG data model conforms to the Network Management Datastore Architecture (NMDA) defined in [RFC8342]. Examples of the usage of these models can be found in Appendix D, Appendix E and Appendix F.

In summary, the objectives of this document are:

- o To describe the architecture for the I2NSF-based IPsec management, which allows the establishment and management of IPsec security associations from the I2NSF Controller in order to protect specific data flows between two flow-based NSFs implementing IPsec.
- o To map this architecture to the I2NSF Framework.
- o To define the interfaces required to manage and monitor the IPsec SAs in the NSF from a I2NSF Controller. YANG data models are defined for configuration and state data for IPsec and IKEv2 management through the I2NSF NSF-Facing interface. Thus, this document does not define any new protocol.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Terminology

This document uses the terminology described in [RFC8329], [RFC8192], [RFC4301], [RFC7296], [RFC6241], [ITU-T.Y.3300]. The following term is defined in [ITU-T.Y.3300]:

o Software-Defined Networking.

The following terms are in defined in [RFC8192]:

- o NSF.
- o Flow-based NSF.

The following terms are defined in [RFC4301]:

- o Peer Authorization Database (PAD).
- o Security Associations Database (SAD).
- o Security Policy Database (SPD).

The following term is defined in [RFC6437]:

o Flow/traffic flow.

The following terms is defined in [RFC7296]:

o Internet Key Exchange version 2 (IKEv2).

The following terms are defined in [RFC6241]:

- o Configuration data.
- o Configuration datastore.
- o State date.
- o Startup configuration datastore.
- o Running configuration datastore.

4. SDN-based IPsec management description

As mentioned in <u>Section 1</u>, two cases are considered, depending on whether the NSF implements IKEv2 or not: IKE case and IKE-less case.

4.1. IKE case: IKEv2/IPsec in the NSF

In this case, the NSF implements IPsec with IKEv2 support. The I2NSF Controller is in charge of managing and applying IPsec connection information (determining which nodes need to start an IKEv2/IPsec session, identifying the type of traffic to be protected, deriving and delivering IKEv2 Credentials such as a pre-shared key, certificates, etc.), and applying other IKEv2 configuration parameters (e.g. cryptographic algorithms for establishing an IKEv2 SA) to the NSF necessary for the IKEv2 negotiation.

With these entries, the IKEv2 implementation can operate to establish the IPsec SAs. The I2NSF User establishes the IPsec requirements and information about the end points information (through the I2NSF Consumer-Facing Interface, [RFC8329]), and the I2NSF Controller translates these requirements into IKEv2, SPD and PAD entries that will be installed into the NSF (through the I2NSF NSF-Facing

Interface). With that information, the NSF can just run IKEv2 to establish the required IPsec SA (when the traffic flow needs protection). Figure 1 shows the different layers and corresponding functionality.

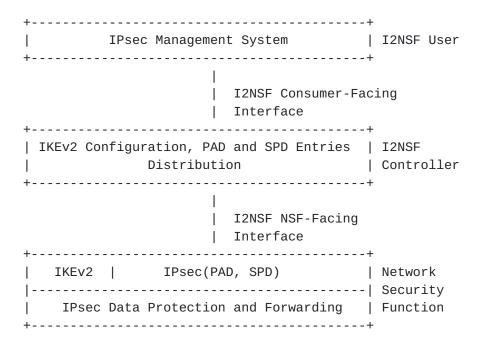

Figure 1: IKE case: IKE/IPsec in the NSF

I2NSF-based IPsec flow protection services provide dynamic and flexible management of IPsec SAs in flow-based NSFs. In order to support this capability in the IKE case, a YANG data model for IKEv2, SPD and PAD configuration data, and for IKEv2 state data MUST be defined for the I2NSF NSF-Facing Interface.

4.2. IKE-less case: IPsec (no IKEv2) in the NSF.

In this case, the NSF does not deploy IKEv2 and, therefore, the I2NSF Controller has to perform the IKEv2 security functions and management of IPsec SAs by populating and managing the SPD and the SAD.

Marin-Lopez, et al. Expires May 3, 2021 [Page 7]

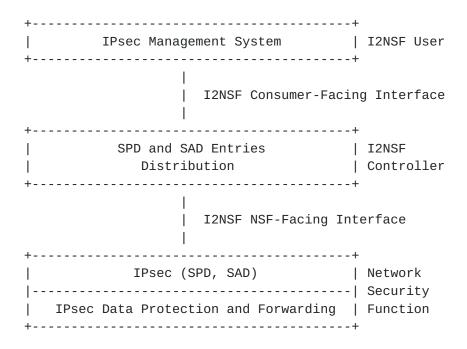

Figure 2: IKE-less case: IPsec (no IKEv2) in the NSF

As shown in Figure 2, when an I2NSF User enforces flow-based protection policies through the Consumer-Facing Interface, the I2NSF Controller translates these requirements into SPD and SAD entries, which are installed in the NSF. PAD entries are not required since there is no IKEv2 in the NSF.

In order to support the IKE-less case, a YANG data model for SPD and SAD configuration data and SAD state data MUST be defined for the NSF-Facing Interface.

Specifically, the IKE-less case assumes that the I2NSF Controller has to perform some security functions that IKEv2 typically does, namely (non-exhaustive):

- o IV generation.
- o Prevent counter resets for the same key.
- o Generation of pseudo-random cryptographic keys for the IPsec SAs.
- o Generation of the IPsec SAs when required based on notifications (i.e. sadb-acquire) from the NSF.
- o Rekey of the IPsec SAs based on notifications from the NSF (i.e. expire).

o NAT Traversal discovery and management.

Additionally to these functions, another set of tasks must be performed by the I2NSF Controller (non-exhaustive list):

- o IPsec SA's SPI random generation.
- o Cryptographic algorithm/s selection.
- o Usage of extended sequence numbers.
- o Establishment of proper traffic selectors.

5. IKE case vs IKE-less case

In principle, the IKE case is easier to deploy than the IKE-less case because current flow-based NSFs (either hosts or gateways) have access to IKEv2 implementations. While gateways typically deploy an IKEv2/IPsec implementation, hosts can easily install it. As downside, the NSF needs more resources to hold IKEv2 such as memory for the IKEv2 implementation, and computation, since each IPsec security association rekeying MAY involve a Diffie-Hellman exchange.

Alternatively, IKE-less case benefits the deployment in resourceconstrained NSFs. Moreover, IKEv2 does not need to be performed in gateway-to-gateway and host-to-host scenarios under the same I2NSF Controller (see Appendix G.1). On the contrary, the complexity of creating and managing IPsec SAs is shifted to the I2NSF Controller since IKEv2 is not in the NSF. As a consequence, this may result in a more complex implementation in the controller side in comparison with IKE case. For example, the I2NSF Controller has to deal with the latency existing in the path between the I2NSF Controller and the NSF, in order to solve tasks such as rekey, or creation and installation of new IPsec SAs. However, this is not specific to this contribution but a general aspect in any SDN-based network. In summary, this complexity MAY create some scalability and performance issues when the number of NSFs is high.

Nevertheless, literature around SDN-based network management using a centralized controller (like the I2NSF Controller) is aware about scalability and performance issues and solutions have been already provided and discussed (e.g. hierarchical controllers; having multiple replicated controllers, dedicated high-speed management networks, etc). In the context of I2SNF-based IPsec management, one way to reduce the latency and alleviate some performance issues can be the installation of the IPsec policies and IPsec SAs at the same time (proactive mode, as described in Appendix G.1) instead of waiting for notifications (e.g. a notification sadb-acquire when a

Marin-Lopez, et al. Expires May 3, 2021 [Page 9]

new IPsec SA is required) to proceed with the IPsec SA installation (reactive mode). Another way to reduce the overhead and the potential scalability and performance issues in the I2NSF Controller is to apply the IKE case described in this document, since the IPsec SAs are managed between NSFs without the involvement of the I2NSF Controller at all, except by the initial configuration (i.e. IKEv2, PAD and SPD entries) provided by the I2NSF Controller. Other solutions, such as Controller-IKE

[I-D.carrel-ipsecme-controller-ike], have proposed that NSFs provide their DH public keys to the I2NSF Controller, so that the I2NSF Controller distributes all public keys to all peers. All peers can calculate a unique pairwise secret for each other peer and there is no inter-NSF messages. A rekey mechanism is further described in [I-D.carrel-ipsecme-controller-ike].

In terms of security, IKE case provides better security properties than IKE-less case, as we discuss in section Section 8. The main reason is that the NSFs generate the session keys and not the I2NSF Controller.

<u>5.1</u>. Rekeying process

Performing a rekey for IPsec SAs is an important operation during the IPsec SAs management. With the YANG data models defined in this document the I2NSF Controller can configure and conduct the rekey process. Depending on the case, the rekey process is different.

For the IKE case, the rekeying process is carried out by IKEv2, following the information defined in the SPD and SAD (i.e. based on the IPsec SA lifetime established by the I2NSF Controller using the YANG data model defined in this document). Therefore, IPsec connections will live unless something different is required by the I2NSF User or the I2NSF Controller detects something wrong.

For the IKE-less case, the I2NSF Controller MUST take care of the rekeying process. When the IPsec SA is going to expire (e.g. IPsec SA soft lifetime), it MUST create a new IPsec SA and it MAY remove the old one (if a IPsec SA lifetime has not been defined). This rekeying process starts when the I2NSF Controller receives a sadbexpire notification or it decides so, based on lifetime state data obtained from the NSF. How the I2NSF Controller implements an algorithm for the rekey process is out of the scope of this document. Nevertheless, an example of how this rekey could be performed is in Appendix G.2.

Marin-Lopez, et al. Expires May 3, 2021 [Page 10]

5.2. NSF state loss.

If one of the NSF restarts, it will lose the IPsec state (affected NSF). By default, the I2NSF Controller can assume that all the state has been lost and therefore it will have to send IKEv2, SPD and PAD information to the NSF in the IKE case, and SPD and SAD information in the IKE-less case.

In both cases, the I2NSF Controller is aware of the affected NSF (e.g. the NETCONF/TCP connection is broken with the affected NSF, the I2NSF Controller is receiving sadb-bad-spi notification from a particular NSF, etc.). Moreover, the I2NSF Controller keeps a list of NSFs that have IPsec SAs with the affected NSF. Therefore, it knows the affected IPsec SAs.

In the IKE case, the I2NSF Controller will configure the affected NSF with the new IKEv2, SPD and PAD information. It has also to send new parameters (e.g. a new fresh PSK for authentication) to the NSFs which have IKEv2 SAs and IPsec SAs with the affected NSF. Finally, the I2NSF Controller will instruct the affected NSF to start the IKEv2 negotiation with the new configuration.

Alternatively, IKEv2 configuration MAY be made permanent between NSFs reboots without compromising security by means of the startup configuration datastore in the NSF. This way, each time a NSF reboots it will use that configuration for each rebooting. It would imply avoiding to contact with the I2NSF Controller.

In the IKE-less case, the I2NSF Controller SHOULD delete the old IPsec SAs in the non-failed nodes established with the affected NSF. Once the affected node restarts, the I2NSF Controller MUST take the necessary actions to reestablish IPsec protected communication between the failed node and those others having IPsec SAs with the affected NSF. How the I2NSF Controller implements an algorithm for managing a potential NSF state loss is out of the scope of this document. Nevertheless, an example of how this could be performed is described in Appendix G.3.

5.3. NAT Traversal

In the IKE case, IKEv2 already provides a mechanism to detect whether some of the peers or both are located behind a NAT. If there is a NAT network configured between two peers, it is required to activate the usage of UDP or TCP/TLS encapsulation for ESP packets ([RFC3948], [RFC8229]). Note that the usage of IPsec transport mode when NAT is required MUST NOT be used in this specification.

Marin-Lopez, et al. Expires May 3, 2021 [Page 11]

In the IKE-less case, the NSF does not have the assistance of the IKEv2 implementation to detect if it is located behind a NAT. If the NSF does not have any other mechanism to detect this situation, the I2NSF Controller SHOULD implement a mechanism to detect that case. The SDN paradigm generally assumes the I2NSF Controller has a view of the network under its control. This view is built either by requesting information from the NSFs under its control, or by information pushed from the NSFs to the I2NSF Controller. Based on this information, the I2NSF Controller MAY guess if there is a NAT configured between two hosts, and apply the required policies to both NSFs besides activating the usage of UDP or TCP/TLS encapsulation of ESP packets ([RFC3948], [RFC8229]). The interface for discovering if the NSF is behind a NAT is out of scope of this document.

If the I2NSF Controller does not have any mechanism to know whether a host is behind a NAT or not, then the IKE-case MUST be used and not the IKE-less case.

5.4. NSF registration and discovery

NSF registration refers to the process of facilitating the I2NSF Controller information about a valid NSF such as certificate, IP address, etc. This information is incorporated in a list of NSFs under its control

The assumption in this document is that, for both cases, before a NSF can operate in this system, it MUST be registered in the I2NSF Controller. In this way, when the NSF starts and establishes a connection to the I2NSF Controller, it knows that the NSF is valid for joining the system.

Either during this registration process or when the NSF connects with the I2NSF Controller, the I2NSF Controller MUST discover certain capabilities of this NSF, such as what is the cryptographic suite supported, authentication method, the support of the IKE case and/or the IKE-less case, etc.

The registration and discovery processes are out of the scope of this document.

6. YANG configuration data models

In order to support the IKE and IKE-less cases we have modeled the different parameters and values that must be configured to manage IPsec SAs. Specifically, the IKE case requires modeling IKEv2 configuration parameters, SPD and PAD, while the IKE-less case requires configuration models for the SPD and SAD. We have defined three models: ietf-i2nsf-ikec (Appendix A, common to both cases),

Marin-Lopez, et al. Expires May 3, 2021 [Page 12]

ietf-i2nsf-ike (Appendix B, IKE case), ietf-i2nsf-ikeless (Appendix C, IKE-less case). Since the model ietf-i2nsf-ikec has only typedef and groupings common to the other modules, we only show a simplified view of the ietf-i2nsf-ike and ietf-i2nsf-ikeless models.

6.1. IKE case model

The model related to IKEv2 has been extracted from reading IKEv2 standard in [RFC7296], and observing some open source implementations, such as Strongswan [strongswan] or Libreswan [libreswan].

The definition of the PAD model has been extracted from the specification in section 4.4.3 in [RFC4301] (NOTE: We have observed that many implementations integrate PAD configuration as part of the IKEv2 configuration).

The data model for the IKE case is defined by YANG model "ietf-i2nsfike". Its structure is depicted in the following diagram, using the notation syntax for YANG tree diagrams ([RFC8340]).

The data model consists of a unique "ipsec-ike" container defined as follows. Firstly, it contains a "pad" container that serves to configure the Peer Authentication Database with authentication information about local and remote peers. More precisely, it consists of a list of entries, each one indicating the identity, authentication method and credentials that will use a particular peer.

Next, we find a list "conn-entry" with information about the different IKE connections a peer can maintain with others. Each connection entry is composed of a wide number of parameters to configure different aspects of a particular IKE connection between two peers: local and remote peer authentication information; IKE SA configuration (soft and hard lifetimes, cryptographic algorithms, etc.); list of IPsec policies describing the type of network traffic to be secured (local/remote subnet and ports, etc.) and how must be protected (AH/ESP, tunnel/transport, cryptographic algorithms, etc.); CHILD SA configuration (soft and hard lifetimes); and, state information of the IKE connection (SPIs, usage of NAT, current expiration times, etc.).

Lastly, the "ipsec-ike" container declares a "number-ike-sas" container to specify state information reported by the IKE software related to the amount of IKE connections established.

Appendix D shows an example of IKE case configuration for a NSF, in tunnel mode (gateway-to-gateway), with NSFs authentication based on X.509 certificates.

6.2. IKE-less case model

For this case, the definition of the SPD model has been mainly extracted from the specification in section 4.4.1 and Appendix D in [RFC4301], though with some changes, namely:

- o Each IPsec policy (spd-entry) contains one traffic selector, instead of a list of them. The reason is that we have observed actual kernel implementations only admit a single traffic selector per IPsec policy.
- o Each IPsec policy contains a identifier (regid) to relate the policy with the IPsec SA. This is common in Linux-based systems.
- o Each IPsec policy has only one name and not a list of names.
- o Combined algorithms have been removed because encryption algorithms MAY include authenticated encryption with associated data (AEAD).
- o Tunnel information has been extended with information about DSCP mapping and ECN bit. The reason is that we have observed real kernel implementations accept configuration of these values.

The definition of the SAD model has been mainly extracted from the specification in section 4.4.2 in [RFC4301] though with some changes, namely:

- o Each IPsec SA (sad-entry) contains one traffic selector, instead of a list of them. The reason is that we have observed actual kernel implementations only admit a single traffic selector per IPsec SA.
- o Each IPsec SA contains a identifier (regid) to relate the IPsec SA with the IPsec Policy. The reason is that we have observed real kernel implementations allow to include this value.
- o Each IPsec SA has also a name in the same way as IPsec policies.
- o Combined algorithm has been removed because encryption algorithm MAY include authenticated encryption with associated data (AEAD).
- o Tunnel information has been extended with information about Differentiated Services Code Point (DSCP) mapping and Explicit

Marin-Lopez, et al. Expires May 3, 2021 [Page 17]

Congestion Notificsation (ECN) bit. The reason is that we have observed actual kernel implementations admit the configurations of these values.

- o Lifetime of the IPsec SAs also include idle time and number of IP packets as threshold to trigger the lifetime. The reason is that we have observed actual kernel implementations allow to set these types of lifetimes.
- o Information to configure the type of encapsulation (encapsulationtype) for IPsec ESP packets in UDP ([RFC3948]), TCP ([RFC8229]) or TLS ([RFC8229]) has been included.

The notifications model has been defined using as reference the PF KEYv2 standard in [RFC2367].

The data model for the IKE-less case is defined by YANG model "ietfi2nsf-ikeless". Its structure is depicted in the following diagram, using the notation syntax for YANG tree diagrams ([RFC8340]).

```

The data model consists of a unique "ipsec-ikeless" container which, in turn, is integrated by two additional containers: "spd" and "sad". The "spd" container consists of a list of entries that conform the Security Policy Database. Compared to the IKE case data model, this part specifies a few additional parameters necessary due to the absence of an IKE software in the NSF: traffic direction to apply the IPsec policy, and a value to link an IPsec policy with its associated IPsec SAs. The "sad" container is a list of entries that conform the Security Association Database. In general, each entry allows to specify both configuration information (SPI, traffic selectors, tunnel/transport mode, cryptographic algorithms and keying material, soft/hard lifetimes, etc.) as well as state information (time to expire, replay statistics, etc.) of a concrete IPsec SA.

In addition, the module defines a set of notifications to allow the NSF inform I2NSF controller about relevant events such as IPsec SA expiration, sequence number overflow or bad SPI in a received packet.

Appendix E shows an example of IKE-less case configuration for a NSF, in transport mode (host-to-host), with NSFs authentication based on shared secrets. For the IKE-less case, Appendix F shows examples of IPsec SA expire, acquire, sequence number overflow and bad SPI notifications.

7. IANA Considerations

This document registers three URIs in the "ns" subregistry of the IETF XML Registry [RFC3688]. Following the format in [RFC3688], the following registrations are requested:

Marin-Lopez, et al. Expires May 3, 2021 [Page 21]

URI: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ikec

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ike

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ikeless

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers three YANG modules in the "YANG Module Names" registry [RFC6020]. Following the format in [RFC6020], the following registrations are requested:

Name: ietf-i2nsf-ikec

Namespace: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ikec

Prefix: nsfikec Reference: RFC XXXX

Name: ietf-i2nsf-ike

Namespace: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ike

Prefix: nsfike Reference: RFC XXXX

Name: ietf-i2nsf-ikeless

Namespace: urn:ietf:params:xml:ns:yang:ietf-i2nsf-ikeless

nsfikels Prefix: Reference: RFC XXXX

8. Security Considerations

First of all, this document shares all the security issues of SDN that are specified in the "Security Considerations" section of [ITU-T.Y.3300] and [RFC7426].

On the one hand, it is important to note that there MUST exist a security association between the I2NSF Controller and the NSFs to protect the critical information (cryptographic keys, configuration parameter, etc.) exchanged between these entities.

On the other hand, if encryption is mandatory for all traffic of a NSF, its default policy MUST be to drop (DISCARD) packets to prevent cleartext packet leaks. This default policy MUST be pre-configured in the startup configuration datastore in the NSF before the NSF contacts the I2NSF Controller. Moreover, the startup configuration datastore MUST be also pre-configured with the required ALLOW

Marin-Lopez, et al. Expires May 3, 2021 [Page 22]

policies that allow the NSF to communicate with the I2NSF Controller once the NSF is deployed. This pre-configuration step is not carried out by the I2NSF Controller but by some other entity before the NSF deployment. In this manner, when the NSF starts/reboots, it will always first apply the configuration in the startup configuration before contacting the I2NSF Controller.

Finally, we have divided this section in two parts in order to analyze different security considerations for both cases: NSF with IKEv2 (IKE case) and NSF without IKEv2 (IKE-less case). In general, the I2NSF Controller, as typically in the SDN paradigm, is a target for different type of attacks [SDNSecServ] and [SDNSecurity]. Thus, the I2NSF Controller is a key entity in the infrastructure and MUST be protected accordingly. In particular, the I2NSF Controller will handle cryptographic material thus the attacker may try to access this information. Although we can assume this attack is not likely to happen due to the assumed security measurements to protect the I2NSF Controller, it still deserves some analysis in the hypothetical case that the attack occurs. The impact is different depending on the IKE case or IKE-less case.

8.1. IKE case

In the IKE case, the I2NSF Controller sends IKEv2 credentials (PSK, public/private keys, certificates, etc.) to the NSFs using the security association between I2NSF Controller and NSFs. The I2NSF Controller MUST NOT store the IKEv2 credentials after distributing them. Moreover, the NSFs MUST NOT allow the reading of these values once they have been applied by the I2NSF Controller (i.e. write only operations). One option is to always return the same value (i.e. all Os) if a read operation is carried out.

If the attacker has access to the I2NSF Controller during the period of time that key material is generated, it might have access to the key material. Since these values are used during NSF authentication in IKEv2, it may impersonate the affected NSFs. Several recommendations are important.

- o IKEv2 configurations should adhere to the recommendations in [RFC8247]
- o If PSK authentication is used in IKEv2, the I2NSF Controller MUST remove the PSK immediately after generating and distributing it.
- o When public/private keys are used, the I2NSF Controller MAY generate both public key and private key. In such a case, the I2NSF Controller MUST remove the associated private key immediately after distributing them to the NSFs. Alternatively,

the NSF could generate the private key and export only the public key to the I2NSF Controller.

o If certificates are used, the NSF MAY generate the private key and export the public key for certification to the I2NSF Controller. How the NSF generates these cryptographic material (public key/ private keys) and exports the public key, is out of scope of this document.

8.2. IKE-less case

In the IKE-less case, the I2NSF Controller sends the IPsec SA information to the NSF's SAD that includes the private session keys required for integrity and encryption. The I2NSF Controller MUST NOT store the keys after distributing them. Moreover, the NSFs receiving private key material MUST NOT allow the reading of these values by any other entity (including the I2NSF Controller itself) once they have been applied (i.e. write only operations) into the NSFs. Nevertheless, if the attacker has access to the I2NSF Controller during the period of time that key material is generated, it may obtain these values. In other words, the attacker might be able to observe the IPsec traffic and decrypt, or even modify and re-encrypt, the traffic between peers.

8.3. YANG modules

The YANG modules specified in this document define a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The Network Configuration Access Control Model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in these YANG modules that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

For the IKE case (ietf-i2nsf-ike):

/ipsec-ike: The entire container in this module is sensitive to write operations. An attacker may add/modify the credentials to be used for the authentication (e.g. to impersonate a NSF), the trust root (e.g. changing the trusted CA certificates), the cryptographic algorithms (allowing a downgrading attack), the IPsec policies (e.g. by allowing leaking of data traffic by changing to a allow policy), and in general changing the IKE SA conditions and credentials between any NSF.

For the IKE-less case (ietf-i2nsf-ikeless):

/ipsec-ikeless: The entire container in this module is sensitive to write operations. An attacker may add/modify/ delete any IPsec policies (e.g. by allowing leaking of data traffic by changing to a allow policy) in the /ipsec-ikeless/ spd container, and add/modify/delete any IPsec SAs between two NSF by means of /ipsec-ikeless/sad container and, in general changing any IPsec SAs and IPsec policies between any NSF.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

For the IKE case (ietf-i2nsf-ike):

/ipsec-ike/pad: This container includes sensitive information to read operations. This information should never be returned to a client. For example, cryptographic material configured in the NSFs: peer-authentication/pre-shared/secret and peerauthentication/digital-signature/private-key are already protected by the NACM extension "default-deny-all" in this document.

For the IKE-less case (ietf-i2nsf-ikeless):

/ipsec-ikeless/sad/sad-entry/ipsec-sa-config/esp-sa: This container includes symmetric keys for the IPsec SAs. For example, encryption/key contains a ESP encryption key value and encryption/iv contains a initialization vector value. Similarly, integrity/key has ESP integrity key value. Those values must not be read by anyone and are protected by the NACM extension "default-deny-all" in this document.

Appendix G. Operational use cases examples

G.1. Example of IPsec SA establishment

This appendix exemplifies the applicability of IKE case and IKE-less case to traditional IPsec configurations, that is, host-to-host and gateway-to-gateway. The examples we show in the following assume the existence of two NSFs needing to establish an end-to-end IPsec SA to

protect their communications. Both NSFs could be two hosts that exchange traffic (host-to-host) or gateways (gateway-to-gateway), for example, within an enterprise that needs to protect the traffic between the networks of two branch offices.

Applicability of these configurations appear in current and new networking scenarios. For example, SD-WAN technologies are providing dynamic and on-demand VPN connections between branch offices, or between branches and SaaS cloud services. Besides, IaaS services providing virtualization environments are deployments that often rely on IPsec to provide secure channels between virtual instances (hostto-host) and providing VPN solutions for virtualized networks (gateway-to-gateway).

As we will show in the following, the I2NSF-based IPsec management system (for IKE and IKE-less cases), exhibits various advantages:

- 1. It allows to create IPsec SAs among two NSFs, based only on the application of general Flow-based Protection Policies at the I2NSF User. Thus, administrators can manage all security associations in a centralized point with an abstracted view of the network.
- 2. Any NSF deployed in the system does not need manual configuration, therefore allowing its deployment in an automated manner.

G.1.1. IKE case

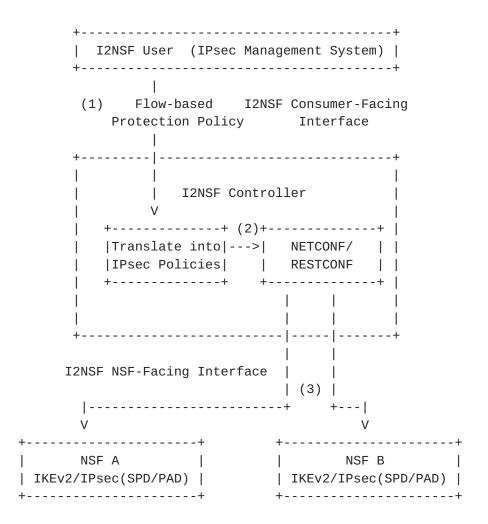

Figure 9: Host-to-host / gateway-to-gateway for the IKE case.

Figure 9 describes the application of the IKE case when a data packet needs to be protected in the path between the NSF A and NSF B:

- 1. The I2NSF User defines a general flow-based protection policy (e.g. protect data traffic between NSF A and B). The I2NSF Controller looks for the NSFs involved (NSF A and NSF B).
- 2. The I2NSF Controller generates IKEv2 credentials for them and translates the policies into SPD and PAD entries.
- 3. The I2NSF Controller inserts an IKEv2 configuration that includes the SPD and PAD entries in both NSF A and NSF B. If some of operations with NSF A and NSF B fail the I2NSF Controller will stop the process and perform a rollback operation by deleting any IKEv2, SPD and PAD configuration that had been successfully installed in NSF A or B.

If the previous steps are successful, the flow is protected by means of the IPsec SA established with IKEv2 between NSF A and NSF B.

G.1.2. IKE-less case

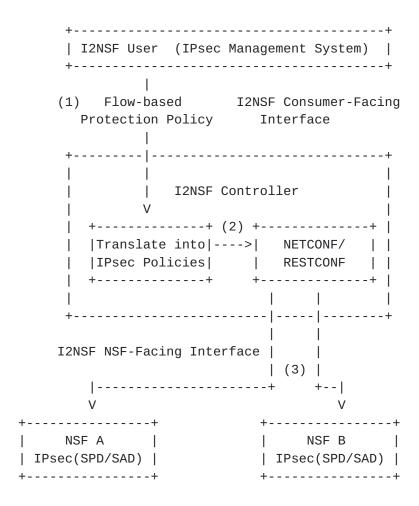

Figure 10: Host-to-host / gateway-to-gateway for IKE-less case.

Figure 10 describes the application of the IKE-less case when a data packet needs to be protected in the path between the NSF A and NSF B:

- 1. The I2NSF User establishes a general Flow-based Protection Policy and the I2NSF Controller looks for the involved NSFs.
- 2. The I2NSF Controller translates the flow-based security policies into IPsec SPD and SAD entries.
- The I2NSF Controller inserts these entries in both NSF A and NSF B IPsec databases (SPD and SAD). The following text describes how this would happen:

- The I2NSF Controller chooses two random values as SPIs: for example, SPIa1 for NSF A and SPIb1 for NSF B. These numbers MUST NOT be in conflict with any IPsec SA in NSF A or NSF B. It also generates fresh cryptographic material for the new inbound/outbound IPsec SAs and their parameters.
- * After that, the I2NSF Controller sends simultaneously the new inbound IPsec SA with SPIa1 and new outbound IPsec SA with SPIb1 to NSF A; and the new inbound IPsec SA with SPIb1 and new outbound IPsec SA with SPIa1 to B, together with the corresponding IPsec policies.
- Once the I2NSF Controller receives confirmation from NSF A and NSF B, it knows that the IPsec SAs are correctly installed and ready.

Other alternative to this operation is: the I2NSF Controller sends first the IPsec policies and new inbound IPsec SAs to A and B and once it obtains a successful confirmation of these operations from NSF A and NSF B, it proceeds with installing to the new outbound IPsec SAs. Even though this procedure may increase the latency to complete the process, no traffic is sent over the network until the IPsec SAs are completely operative. In any case other alternatives MAY be possible to implement step 3.

- 4. If some of the operations described above fail (e.g. the NSF A reports an error when the I2NSF Controller is trying to install the SPD entry, the new inbound or outbound IPsec SAs) the I2NSF Controller MUST perform rollback operations by deleting any new inbound or outbound SA and SPD entry that had been successfully installed in any of the NSFs (e.g NSF B) and stop the process. Note that the I2NSF Controller may retry several times before giving up.
- 5. Otherwise, if the steps 1 to 3 are successful, the flow between NSF A and NSF B is protected by means of the IPsec SAs established by the I2NSF Controller. It is worth mentioning that the I2NSF Controller associates a lifetime to the new IPsec SAs. When this lifetime expires, the NSF will send a sadb-expire notification to the I2NSF Controller in order to start the rekeying process.

Instead of installing IPsec policies (in the SPD) and IPsec SAs (in the SAD) in step 3 (proactive mode), it is also possible that the I2NSF Controller only installs the SPD entries in step 3 (reactive mode). In such a case, when a data packet requires to be protected with IPsec, the NSF that saw first the data packet will send a sadbacquire notification that informs the I2NSF Controller that needs SAD entries with the IPsec SAs to process the data packet. Again, if some of the operations installing the new inbound/outbound IPsec SAs fail, the I2NSF Controller stops the process and performs a rollback operation by deleting any new inbound/outbound SAs that had been successfully installed.

<u>G.2</u>. Example of the rekeying process in IKE-less case

To explain an example of the rekeying process between two IPsec NSFs A and B, let assume that SPIa1 identifies the inbound IPsec SA in A, and SPIb1 the inbound IPsec SA in B. The rekeying process will take the following steps:

- 1. The I2NSF Controller chooses two random values as SPI for the new inbound IPsec SAs: for example, SPIa2 for A and SPIb2 for B. These numbers MUST NOT be in conflict with any IPsec SA in A or B. Then, the I2NSF Controller creates an inbound IPsec SA with SPIa2 in A and another inbound IPsec SA in B with SPIb2. It can send this information simultaneously to A and B.
- 2. Once the I2NSF Controller receives confirmation from A and B, the controller knows that the inbound IPsec SAs are correctly installed. Then it proceeds to send in parallel to A and B, the outbound IPsec SAs: the outbound IPsec SA to A with SPIb2, and the outbound IPsec SA to B with SPIa2. At this point the new IPsec SAs are ready.
- 3. Once the I2NSF Controller receives confirmation from A and B that the outbound IPsec SAs have been installed, the I2NSF Controller, in parallel, deletes the old IPsec SAs from A (inbound SPIa1 and outbound SPIb1) and B (outbound SPIa1 and inbound SPIb1).

If some of the operations in step 1 fail (e.g. the NSF A reports an error when the I2NSF Controller is trying to install a new inbound IPsec SA) the I2NSF Controller MUST perform rollback operations by removing any new inbound SA that had been successfully installed during step 1.

If step 1 is successful but some of the operations in step 2 fails (e.g. the NSF A reports an error when the I2NSF Controller is trying to install the new outbound IPsec SA), the I2NSF Controller MUST perform a rollback operation by deleting any new outbound SA that had been successfully installed during step 2 and by deleting the inbound SAs created in step 1.

If the steps 1 and 2 are successful but the step 3 fails, the I2NSF Controller will avoid any rollback of the operations carried out in Marin-Lopez, et al. Expires May 3, 2021 [Page 91]

step 1 and step 2 since new and valid IPsec SAs were created and are functional. The I2NSF Controller may reattempt to remove the old inbound and outbound SAs in NSF A and NSF B several times until it receives a success or it gives up. In the last case, the old IPsec SAs will be removed when their corresponding hard lifetime is reached.

<u>G.3</u>. Example of managing NSF state loss in IKE-less case

In the IKE-less case, if the I2NSF Controller detects that a NSF has lost the IPsec state, it could follow the next steps:

- 1. The I2NSF Controller SHOULD delete the old IPsec SAs on the nonfailed nodes, established with the failed node. This prevents the non-failed nodes from leaking plaintext.
- 2. If the affected node restarts, the I2NSF Controller configures the new inbound IPsec SAs between the affected node and all the nodes it was talking to.
- 3. After these inbound IPsec SAs have been established, the I2NSF Controller configures the outbound IPsec SAs in parallel.

Step 2 and step 3 can be performed at the same time at the cost of a potential packet loss. If this is not critical then it is an optimization since the number of exchanges between I2NSF Controller and NSFs is lower.
