Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for information related to a Fibre Channel network's Fabric Address Manager. In the past, this memo was a work item of T11.5 (<http://www.t11.org>). After T11 approved it, it became a work item of the IETF's IMSS working group.

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for information related to a Fibre Channel network's Fabric Address Manager. Fabric Address Manager refers to the functionality of acquiring DomainID(s) as specified in [[FC-SW-3](#)], and managing Fibre Channel Identifiers as specified in [[FC-FS](#)].

1.1. Log of Recent Changes

This section to be deleted when the document becomes approved.

1.1.1. Initial version

The initial version was submitted to T11.5 as 04-079v0 on 18 January 2004 (at that time, it was called the Fibre Channel Domain Manager MIB).

1.1.2. 16 February 2005 version

The following changes were made for the version was submitted to the IETF as: [draft-ietf-imss-fc-fam-mib-01.txt](#).

- t11FamEnable & t11FamFabricName were added as additional objects in the t11FamTable. A strong warning was included concerning the need for a Fabric name (the value of t11FamFabricName) to be the same on all switches in a Fabric.
- an additional enumeration, 'disabled(11)', was added to T11FamState.
- the syntax and DESCRIPTIONs of t11FamConfigDomainId & t11FamConfigDomainIdType were modified.
- the syntax of T11FabricIndex was updated to have a range of (0..4095) so as to be consistent with [[FC-SW-4](#)], for which the 22 October 2004 version says that a "VF_ID Bitmap" is 512 bytes long, with the high-order bit representing VF_ID zero, and the low-order bit representing 4095.

2. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to [section 7 of RFC 3410](#) [[RFC3410](#)].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, [RFC 2578](#) [[RFC2578](#)], STD 58, [RFC 2579](#) [[RFC2579](#)] and STD 58, [RFC 2580](#) [[RFC2580](#)].

3. Short Overview of Fibre Channel

The Fibre Channel (FC) is logically a bidirectional point-to-point serial data channel, structured for high performance. Fibre Channel provides a general transport vehicle for higher level protocols such as Small Computer System Interface (SCSI) command sets, the High-Performance Parallel Interface (HIPPI) data framing, IP (Internet Protocol), IEEE 802.2, and others.

Physically, Fibre Channel is an interconnection of multiple communication points, called N_Ports, interconnected either by a switching network, called a Fabric, or by a point-to-point link. A Fibre Channel "node" consists of one or more N_Ports. A Fabric may consist of multiple Interconnect Elements, some of which are switches. An N_Port connects to the Fabric via a port on a switch called an F_Port. When multiple FC nodes are connected to a single port on a switch via an "Arbitrated Loop" topology, the switch port is called an FL_Port, and the nodes' ports are called NL_Ports. The term Nx_Port is used to refer to either an N_Port or an NL_Port. The term Fx_Port is used to refer to either an F_Port or an FL_Port. A switch port, which is interconnected to another switch port via an Inter Element Link (IEL), is called an E_Port. A B_Port connects a bridge device with an E_Port on a switch; a B_Port provides a subset of E_Port functionality.

Many Fibre Channel components, including the fabric, each node, and most ports, have globally-unique names. These globally-unique names are typically formatted as World Wide Names (WWNs). More information on WWNs can be found in [[FC-FS](#)]. WWNs are expected to be persistent

Expires August 2005

[Page 4]

across agent and unit resets.

Fibre Channel frames contain 24-bit address identifiers which identify the frame's source and destination ports. Each FC port has both an address identifier and a WWN. When a fabric is in use, the FC address identifiers are dynamically assigned by a switch. Each octet of a 24-bit address represents a level in an address hierarchy, with a Domain_ID being the highest level of the hierarchy.

Each Switch in a Fabric is assigned one (or more) unique Domain_IDs using a two-step process. First, one switch, called Principal Switch, is selected from the switches of a Fabric. Then, the Principal Switch assigns Domain_IDs to the other switches of the Fabric. Address assignment within a Domain is performed by the switch to which that Domain_ID is granted.

4. Relationship to Other MIBs

The first standardized MIB for Fibre Channel [[RFC2837](#)] was focused on Fibre Channel switches. It is being replaced by the more generic Fibre Channel Management MIB [[FC-MGMT](#)] which defines basic information for Fibre Channel hosts and switches, including extensions to the standard IF-MIB [[RFC2863](#)] for Fibre Channel interfaces. [[FC-MGMT](#)] includes the specification of how the generic objects defined in [[IF-MIB](#)] apply to Fibre Channel interfaces.

Note that an interface's ifIndex value must be unique within an SNMP context, irrespective of how many Fibre Channel management instances (see below) and how many Fibre Channel switches are instrumented within that SNMP context.

This document defines the T11-FC-FABRIC-ADDR-MGR-MIB module which extends beyond [[FC-MGMT](#)] to cover the functionality, in Fibre Channel switches, which is used to manage fabric configuration, domains, and addresses within a domain.

This document also contains a MIB module, T11-TC-MIB, to define Textual Conventions which might also be useful in other MIBs defined by T11.

5. MIB Overview

This section explains the use of a Fibre Channel management instance, a Switch Index, and a Fabric Index. It also describes the six MIB groups contained in the MIB.

5.1. Fibre Channel management instance

A Fibre Channel management instance is defined in [[FC-MGMT](#)] as a separable managed instance of Fibre Channel functionality. Fibre Channel functionality may be grouped into Fibre Channel management instances in whatever way is most convenient for the implementation(s). For example, one such grouping accommodates a single SNMP agent having multiple AgentX [[RFC2741](#)] sub-agents, with each sub-agent implementing a different Fibre Channel management instance.

The object, fcmInstanceIndex, is IMPORTed from the FC-MGMT-MIB [[FC-MGMT](#)] as the index value to uniquely identify a Fibre Channel management instance.

5.2. Switch Index

The FC-MGMT-MIB [[FC-MGMT](#)] defines the fcmSwitchTable as a table of information about Fibre Channel switches which are managed by Fibre Channel management instances. Each Fibre Channel management instance can manage one or more Fibre Channel switches. The Switch Index, fcmSwitchIndex, is IMPORTed from the FC-MGMT-MIB as the index value to uniquely identify a Fibre Channel switch amongst those (one or more) managed by the same Fibre Channel management instance.

5.3. Fabric Index

The current standard for an interconnecting Fabric consisting of multiple Fabric Switch elements is [[FC-SW-3](#)], which describes the operation of a single Fabric in a physical infrastructure. Forthcoming standards, e.g., [[FC-SW-4](#)], will likely define how multiple Fabrics could operate within one (or more) physical infrastructures. In such a scenario, each Fabric would, of course, have its own management instrumentation. Therefore, to allow for this possibility, this MIB defines all Fabric-related information in tables which are INDEX-ed by an arbitrary integer, named a "Fabric Index". In a Fabric which is conformant to [[FC-SW-3](#)], the value of this Fabric Index will always be 1.

It is quite possible, and may even become likely, that (a port of) a Fibre Channel switch will be connected to multiple such Fabrics. Thus, in order to simplify a query concerning all the Fabrics to which a single switch is connected, fcmSwitchIndex will be listed before t11FamFabricIndex when they both appear in the same INDEX clause.

5.4. The t11FamGroup group

This group contains basic information about the Fabric Address Manager functionality within a switch, including its configuration parameters which are per-interface (i.e., specified for a particular Fibre Channel interface identified by an ifIndex value).

5.5. The t11FamDatabaseGroup group

This group contains information about which switches are assigned to which domains.

5.6. The t11FamAreaGroup group

This group contains information about which Port-IDs have been assigned within the Areas of the local Domain.

5.7. The t11FamCacheGroup group

This conditional mandatory group contains information about all the FC address identifier assignments which have been recently released. This cache is kept to support the concept of Preferred Domain_ID via a best effort attempt for (short-term) re-assignment of the same FC address identifiers.

5.8. The t11FamCommandGroup group

This optional group contains objects used for initiating an operation on a Fabric.

5.9. The t11FamNotificationGroup group

This group contains notifications of significant events concerning the Fabric Address management functionality within a switch.

5.10. Use of RCF and BF

Included in [[FC-SW-3](#)] is the specification of Reconfigure Fabric (RCF) and Build Fabric (BF), both of which are command-codes of the Switch Fabric Internal Link Service (SW_ILS). [[FC-SW-3](#)] includes the warning:

NOTE 13 - Since the RCF causes a complete reconfiguration of the Fabric, and may cause addresses allocated to a Switch to change, this SW_ILS should be used with caution. The BF SW_ILS allows the Fabric to attempt reconfiguration without loss of or change of address and therefore should be attempted before an RCF. Examples of situations in which RCF may be appropriate include resolution of overlapped Domains, or the failure of a Fabric Reconfiguration initiated by a BF.

Further, [[FC-MI](#)] specifies

A Fabric is prohibited from autonomously generating a RCF, but an outside administrative function may request a switch to generate an RCF. Such an administrative function is outside the scope of this technical report.

The T11-FC-FABRIC-ADDR-MGR-MIB defined in this document is consistent with both of the above quotes since it defines two objects, t11FamAutoReconfigure and t11FamRestart, which are defined with a MAX-ACCESS of read-write, and setting them to the appropriate value is a means by which "an outside administrative function may request a switch to generate an RCF" [[FC-MI](#)].

Note, however, the MIB specifies in its compliance section that the minimum required level of support for these two objects is read-only.

Further, for both t11FamAutoReconfigure and t11FamRestart, the MIB serves only as a request to generate; it does not represent the action of the RCF or BF. That is, a successful SNMP SetRequest on these objects will cause an RCF (or BF) to be sent, but SNMP does not/can not ensure the successful operation of the SW_ILS operation.

t11FamFabricIndex OBJECT-TYPE
 SYNTAX T11FabricIndex
 MAX-ACCESS not-accessible
 STATUS current
 DESCRIPTION

"A unique index value which uniquely identifies a particular Fabric known to a particular switch.

In a Fabric conformant to SW-3, only a single Fabric can operate within a physical infrastructure, and thus, the value of this Fabric Index will always be 1.

However, forthcoming standards (e.g., FC-SW-4), will likely define how multiple Fabrics, each with its own management instrumentation, could operate within one (or more) physical infrastructures. To allow for such multiple fabrics, this index value is used to uniquely identify a particular Fabric within a physical infrastructure."

::= { t11FamEntry 1 }

t11FamConfigDomainId OBJECT-TYPE

SYNTAX FcDomainIdOrZero

MAX-ACCESS read-write

STATUS current

DESCRIPTION

"The configured Domain_ID of the particular switch on this Fabric, or zero if no Domain_ID has been configured. The meaning of this object depends on t11FamConfigDomainIdType object.

If t11FamConfigDomainIdType is 'preferred', then the configured Domain_ID is called the 'preferred Domain_ID'. Valid values are between 0 and 239. In a situation where this Domain_ID can not be assigned, any other Domain_ID will be acceptable. A value of zero means any Domain_ID.

If t11FamConfigDomainIdType is 'insistent', then the configured Domain_ID is called the 'insistent Domain_ID' and valid values are between 1 and 239. In a situation where this Domain_ID can not be assigned, no other Domain_ID is acceptable.

In both of the above cases, the switch sends an RDI (Request Domain_ID) to request this Domain_ID to the Principal Switch. If no Domain_ID is able to be granted in the case of 'preferred', or if an 'insistent' Domain_ID is configured but not able to be granted, then it is an error condition. When this error occurs, the switch will continue as if it receives a SW_RJT with a reason/explanation of 'Unable to perform command request'/'Domain_ID not available'. That is, its E_Ports on that Fabric will be isolated and the administrator informed via a 't11FamDomainIdNotAssigned' notification.

If t11FamConfigDomainIdType is 'static', then the configured Domain_ID is called the 'static Domain_ID' and valid values are between 1 and 239. In this situation, there is no Principal Switch in the Fabric and the Domain_ID is simply assigned by configuration, together with the Fabric_Name. A switch configured with a static Domain_ID, on receiving an EFP, BF, RCF, DIA or RDI SW_ILS shall reply with an SW_RJT having Reason Code Explanation 'E_Port is Isolated' and shall isolate the receiving E_Port."

Rev 7.1, October 2004, sections [7.1](#) and [7.3](#)."

DEFVAL { true }
::= { t11FamEntry 26 }

t11FamFabricName OBJECT-TYPE
SYNTAX FcNameIdOrZero
MAX-ACCESS read-write
STATUS current
DESCRIPTION

"The WWN that is configured on this switch to be used as
the name of this Fabric when the value of t11FamEnable is
'false'.

If the value of t11FamEnable is 'true', this value is not
used.

Fibre Channel requires that:

- a) all switches in an operational Fabric be
configured with the same Fabric name, and
- b) each Fabric have a unique Fabric name.

If either of these is violated, either by switches within a
single Fabric being configured with different Fabric names,
or by multiple Fabrics that share management applications
or interact in other ways having the same Fabric name,
then the behavior of the switches and associated management
functions is not specified by Fibre Channel or Internet
standards."

--

-- t11FamIfTable - Interface configuration

--

t11FamIfTable OBJECT-TYPE
SYNTAX SEQUENCE OF T11FamIfEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION

"This table contains those Fabric Address Manager parameters

and status values, which are per-interface (identified by an ifIndex value), per-Fabric (identified by a t11FamFabricIndex value), and per-switch (identified by values of fcmInstanceIndex and fcmSwitchIndex).

An entry in this table is automatically created when an E_Port becomes non-isolated on a particular Fabric.

An entry is deleted automatically from this table if:

- a) the corresponding interface is no longer an E_Port (e.g., a G_Port which is dynamically determined to be an F_Port), and all configuration parameter(s) have default values; or
- b) the interface identified by ifIndex no longer exists (e.g., because a line-card is physically removed); or
- c) the row in the t11FamTable corresponding the fabric identified by t11FamFabricID no longer exists.

Creating an entry in this table via t11FamIfRowStatus provides the means to specify non-default parameter value(s) for an interface at a time when the relevant row in this table does not exist, i.e., because the interface is either down or it is not an E_Port."

11. IANA Considerations

IANA is requested to make the OID assignments for both MIB modules under the appropriate subtree.

12. Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

t11FamConfigDomainId, t11FamConfigDomainIdType and
t11FamContiguousAllocation -- ability to change the address
allocation policy.

t11FamRestart and t11FamAutoReconfigure -- ability to cause a
fabric reconfiguration, e.g., on certain error conditions.

t11FamPriority -- ability to affect which switch becomes the
Principal switch.

t11FamRcFabricNotifyEnabl -- ability to enable/disable a
notification.

t11FamIfRcfReject -- ability to change the switch's behaviour on
receipt of an RCF.

t11FamIfRowStatus -- ability to change an interface
configuration parameter.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may also be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

t11FamTable and t11FamIfTable -- contain the configuration,
status and statistics of the Fabric Address Manager.

t11FamAreaTable, t11FamDatabaseTable and t11FamFcIdCacheTable -- contain information on currently assigned or recently-released addresses.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementors consider the security features as provided by the SNMPv3 framework (see [\[RFC3410\]](#), [section 8](#)), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
