Optical Network Service Requirements

Status of This Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC2026](#). Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or rendered obsolete by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress".

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

Abstract

This Internet Draft describes the major carrier's optical service requirements for the Automatically Switched Optical Networks (ASON) from both an end-user's as well as an operator's perspectives. Its focus is on the description of the service building blocks and service-related control plane functional requirements. The management functions for the optical services and their underlying networks are beyond the scope of this document.

1. Introduction

Optical transport networks are evolving from the current TDM-based SONET/SDH optical networks as defined by ANSI T1.105 and ITU Rec.

G.803 [[ansi-sonet](#), [itu-sdh](#)] to emerging WDM-based optical
transport
networks (OTN) as defined by ITU Rec. G.872 in [[itu-otn](#)].
Therefore in

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 2]

the near future, carrier optical transport networks are expected to consist of a mixture of the SONET/SDH-based sub-networks and the WDM-based wavelength or fiber switched OTN sub-networks. The OTN networks can be either transparent or opaque depending upon if O-E-O functions are utilized within the optical networks. Optical networking encompasses the functionalities for the establishment, transmission, multiplexing and switching of optical connections carrying a wide range of user signals of varying formats and bit rate. The optical connections in this document include switched optical path using TDM channel, WADM wavelength or fiber links.

Some of the challenges for the carriers are efficient bandwidth management and fast service provisioning in a multi-technology and possibly multi-vendor networking environment. The emerging and rapidly evolving Automatically Switched Optical Network (ASON) technology [itu-astn, itu-ason] is aimed at providing optical networks with intelligent networking functions and capabilities in its control plane to enable rapid optical connection provisioning, dynamic rerouting as well as multiplexing and switching at different granularity levels, including fiber, wavelength and TDM channel. The ASON control plane should not only enable the new networking functions and capabilities for the emerging OTN networks, but significantly enhance the service provisioning capabilities for the existing SONET/SDH networks as well.

The ultimate goals should be to allow the carriers to automate network resource and topology discovery, to quickly and dynamically provision network resources and circuits, and to support assorted network survivability using ring and mesh-based protection and restoration techniques. The carriers see that this new networking platform will create tremendous business opportunities for the network operators and service providers to offer new services to the market, and in the long

run to reduce their network operation cost (OpEx saving), and to improve their network utilization efficiency (CapEx saving).

1.1 Conventions Used in This Document

in

this document are to be interpreted as described in [RFC 2119](#).

1.2 Value Statement

By deploying ASON technology, a carrier expects to achieve the following benefits from both technical and business perspectives:
Automated Discovery: ASON technology will enable automatic network inventory management, topology and resource discovery which

eliminates

the manual or semi-manual process for maintaining the network information database that exist in most carrier environment.

dynamic
optical

Rapid Circuit Provisioning: ASON technology will enable the end-to-end provisioning of the optical connections across the network by using standard routing and signaling protocols.

the
to
network.

Enhanced Protection and Restoration: ASON technology will enable network to dynamically reroute an optical connection in case of failure using mesh-based network protection and restoration techniques, which greatly improves the cost-effectiveness compared the current line and ring protection schemes in the SONET/SDH

of an
rate

- Service Flexibility: ASON technology will support provisioning assortment of existing and new services such as protocol and bit-independent transparent network services, and bandwidth-on-demand services.

plane
and

- Enhanced Interoperability: ASON technology will use a control utilizing industry and international standards-based architecture protocols, which facilitate the interoperability of the optical network equipment from different vendors.

potential

In addition, the ASON control plane may offer the following value-added benefits:

network

- Reactive traffic engineering at optical layer that allows resources to be dynamically allocated to traffic flow.

service
deployment

- Reduce the need for service providers to develop new operational support systems (OSS) software for the network control and new provisioning on the optical network, thus speeding up the of the optical network technology and reducing the software development and maintenance cost.

used

- Potential development of a unified control plane that can be for different transport technologies including OTN, SONET/SDH, ATM

and

PDH.

1.3. Scope of this document

This document is intended to provide, from the carriers perspective, a service framework and some associated requirements in relation to the optical transport services to be offered in the next generation optical transport networking environment and their service control and management functions. As such, this document concentrates on the requirements driving the work towards realization of automatically switched optical networks. This document is intended to be protocol-neutral, but the specific goals include providing the requirements to guide the control protocol development and enhancement within IETF in terms of reuse of IP-centric control protocols in the optical transport network.

Every carrier's needs are different. The objective of this document is NOT to define some specific service models. Instead, some major service building blocks are identified that will enable the carriers to use them in order to create the best service platform most suitable to their business model. These building blocks include generic service types, service enabling control mechanisms and service control and management functions.

The Optical Internetworking Forum (OIF) carrier group has developed a comprehensive set of control plane requirements for both UNI and NNI [[oif-carrier](#), [oif-nnireq](#)] and they have been used as the base line input to this document.

The fundamental principles and basic set of requirements for the control plane of the automatic switched optical networks have been provided in a series of ITU Recommendations under the umbrella of ITU ASTN/ASON architectural and functional requirements as listed below:

Architecture:

- ITU-T Rec. G.8070/Y.1301 (2001), Requirements for the Automatic Switched Transport Network (ASTN)[[itu-astn](#)]
- ITU-T Rec. G.8080/Y.1304 (2001), Architecture of the Automatic Switched Optical Network (ASON)[[itu-ason](#)]

Signaling:

- ITU-T Rec. G.7713/Y.1704 (2001), Distributed Call and Connection Management (DCM)[[itu-dcm](#)]

Routing:

- ITU-T Draft Rec. G.7715/Y.1706 (2002), Architecture and Requirements for Routing in the Automatically Switched Optical Network [[itu-rtg](#)]

Discovery:

- ITU-T Rec. G.7714/Y.1705 (2001), Generalized Automatic Discovery [[itu-disc](#)]

Signaling Communication Network:

of - ITU-T Rec. G.7712/Y.1703 (2001), Architecture and Specification
Data Communication Network [itu-dcn]
This document provides further detailed requirements based on the
ASTN/ASON framework. In addition, even though for IP over Optical
we consider IP as a major client to the optical network in this
document,
the same requirements and principles should be equally applicable
to non-IP clients such as SONET/SDH, ATM, ITU G.709, Ethernet, etc.
The general architecture for IP over Optical is described in the IP
over Optical framework document [ipo-frame]

4. General Requirements

the In order to provide the carriers with flexibility and control of
are optical networks, the following set of architectural requirements
essential.

4.1. Separation of Networking Functions

A fundamental architectural principle of the ASON network is to segregate the networking functions within each layer network into

three logical functional planes: control plane, data plane and management plane. They are responsible for providing network control functions, data transmission functions and network management functions respectively. The crux of the ASON network is the networking

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 6]

discovery intelligence that contains automatic routing, signaling and functions to automate the network control functions.

control well Control Plane: includes the functions related to networking capabilities such as routing, signaling, and policy control, as well as resource and service discovery. These functions are automated.

bearer Data Plane (Transport Plane): includes the functions related to channels and signal transmission.

control Management Plane: includes the functions related to the management functions of network element, networks and network resources and services. These functions are less automated as compared to plane functions.

control Each plane consists of a set of interconnected functional or entities, physical or logical, responsible for providing the networking or control functions defined for that network layer.

However, Each plane has clearly defined functional responsibilities.

control the management plane is responsible for the management of both

control and data planes, thus playing an authoritative role in overall and management functions as discussed in [Section 9](#).

management The separation of the control plane from both the data and plane is beneficial to the carriers in that it:

will

- Allows equipment vendors to have a modular system design that be more reliable and maintainable.
- Allows carriers to have the flexibility to choose a third party vendor control plane software systems as the control plane solution for its switched optical network.
- Allows carriers to deploy a unified control plane and OSS/management systems to manage and control different types of transport networks it

owns.

designed

- Allows carriers to use a separate control network specially and engineered for the control plane communications.

The separation of control, management and transport function is required and it shall accommodate both logical and physical level separation. The logical separation refers to functional separation while physical separation refers to the case where the control, management and transport functions physically reside in different equipment or locations.

same

Note that it is in contrast to the IP network where the control messages and user traffic are routed and switched based on the

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 7]

the

network topology due to the associated in-band signaling nature of IP network.

data

[ietf-

When the physical separation is allowed between the control and plane, a standardized interface and control protocol (e.g. GSMP [ietf-gsmp]) should be supported.

4.2. Separation of call and connection control

bandwidth

To support many enhanced optical services, such as scheduled on demand, diverse circuit provisioning and bundled connections, a call model based on the separation of call control and connection control is essential.

while

to

connections

The call control is responsible for the end-to-end session negotiation, call admission control and call state maintenance

connection control is responsible for setting up the connections associated with a call across the network. A call can correspond

zero, one or more connections depending upon the number of needed to support the call.

The existence of the connection depends upon the existence of its associated call session and connection can be deleted and re-established while still keeping the call session up.

port

definition].

The call control shall be provided at an ingress port or gateway to the network such as UNI and E-NNI [see [Section 6](#) for

The connection control is provided at the originating node of the circuit as well as on each link along the path.

The control plane shall support the separation of the call control from the connection control.

setup

The control plane shall support call admission control on call and connection admission control on connection setup.

4.3. Network and Service Scalability

Although some specific applications or networks may be on a small scale, the control plane protocol and functional capabilities

shall

support large-scale networks.

network,

In terms of the scale and complexity of the future optical

scalability

the following assumption can be made when considering the

and performance that are required of the optical control and management functions.

- There may be up to thousands of OXC nodes and the same or higher order of magnitude of OADMs per carrier network.

OXC

- There may be up to thousands of terminating ports/wavelength per node.

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 8]

OXC

- There may be up to hundreds of parallel fibers between a pair of nodes.

on

- There may be up to hundreds of wavelength channels transmitted each fiber.

in

As for the frequency and duration of the optical connections:

- The expected end-to-end connection setup/teardown time should be the order of seconds, preferably less.

- The expected connection holding times should be in the order of minutes or greater.

- There may be up to millions of simultaneous optical connections switched across a single carrier network.

4.4. Transport Network Technology

Optical services can be offered over different types of underlying optical transport technologies including both TDM-based SONET/SDH network and WDM-based OTN networks.

ITU

Standards-based transport technologies SONET/SDH as defined in the

G.709

Rec. G.803 and OTN implementation framing as defined in ITU Rec.

[[itu-g709](#)] shall be supported.

granularity

Note that the service characteristics such as bandwidth

determined

and signaling framing hierarchy to a large degree will be

by the capabilities and constraints of the server layer network.

4.5. Service Building Blocks

One of the goals of this document is to identify a set of basic service building blocks the carriers can use to create the best suitable service models that serve their business needs.

The service building blocks are comprised of a well-defined set of capabilities and a basic set of control and management functions. These capabilities and functions should support a basic set of services and enable a carrier to build enhanced services through extensions and customizations. Examples of the building blocks

include

policy

the connection types, provisioning methods, control interfaces,
control functions, and domain internetworking mechanisms, etc.

5. Service Model and Applications

models.

A carrier's optical network supports multiple types of service

Each service model may have its own service operations, target
markets, and service management requirements.

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 9]

5.1. Service and Connection Types

The optical network is primarily offering optical paths that are bandwidth connections between two client network elements, such as routers or ATM switches, established across the optical network. A connection is also defined by its demarcation from ingress access point, across the optical network, to egress access point of the optical network.

The following connection capability topologies must be supported:

- Bi-directional point-to-point connection
- Uni-directional point-to-point connection
- Uni-directional point-to-multipoint connection

The point-to-point connections are the primary concerns of the carriers. In this case, the following three types of network connections based on different connection set-up control methods

be supported:

- Permanent connection (PC): Established hop-by-hop directly on ONE along a specified path without relying on the network routing signaling capability. The connection has two fixed end-points and fixed cross-connect configuration along the path and stays up until it is deleted. This is similar to the concept of PVC in ATM and there is no automatic re-routing capability.

- Switched connection (SC): Established through UNI signaling interface and the connection is dynamically established by network using the network routing and signaling functions. This is similar to the concept of SVC in ATM.

- Soft permanent connection (SPC): Established by specifying two end-points and let the network dynamically establishes a SC in between. This is similar to the SPVC concept in ATM.

The PC and SPC connections should be provisioned via management

via to control interface and the SC connection should be provisioned
signaled UNI interface.

provisioning Note that even though automated rapid optical connection
circuits, is required, the carriers expect the majority of provisioned
months to at least in short term, to have a long lifespan ranging from
years.

perform In terms of service provisioning, some carriers may choose to
testing prior to turning over to the customer.

5.2. Examples of Common Service Models

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 10]

Each carrier may define its own service model based on its business strategy and environment. The following are example service models that carriers may use.

5.2.1. Provisioned Bandwidth Service (PBS)

The PBS model provides enhanced leased/private line services provisioned via service management interface (MI) using either PC

or

SPC type of connection. The provisioning can be real-time or near real-time. It has the following characteristics:

interface

- Connection request goes through a well-defined management
- Client/Server relationship between clients and optical network.
- Clients have no optical network visibility and depend on network intelligence or operator for optical connection setup.

5.2.2. Bandwidth on Demand Service (BDS)

The BDS model provides bandwidth-on-demand dynamic connection

services

via signaled user-network interface (UNI). The provisioning is

real-

time and is using SC type of optical connection. It has the

following

characteristics:

its

- Signaled connection request via UNI directly from the user or proxy.

- Customer has no or limited network visibility depending upon the control interconnection model used and network administrative

policy.

- Relies on network or client intelligence for connection set-up depending upon the control plane interconnection model used.

5.2.3. Optical Virtual Private Network (OVPN)

The OVPN model provides virtual private network at the optical

layer

between a specified set of user sites. It has the following characteristics:

- Customers contract for specific set of network resources such as optical connection ports, wavelengths, etc.

- Closed User Group (CUG) concept is supported as in normal VPN.
- Optical connection can be of PC, SPC or SC type depending upon the provisioning method used.
- An OVPN site can request dynamic reconfiguration of the connections between sites within the same CUG.

- A customer may have visibility and control of network resources up to the extent allowed by the customer service contract.

At a minimum, the PBS, BDS and OVPN service models described above shall be supported by the control functions.

6. Network Reference Model

components
reference
management
This section discusses major architectural and functional of a generic carrier optical network, which will provide a model for describing the requirements for the control and management of carrier optical services.

6.1. Optical Networks and Sub-networks

that
ITU
As mentioned before, there are two main types of optical networks are currently under consideration: SDH/SONET network as defined in Rec. G.803, and OTN as defined in ITU Rec. G.872.

connects
assume
In the current SONET/SDH-based optical network, digital cross-connects (DXC) and add-drop multiplexer (ADM) and line multiplexer terminal (LMT) are connected in ring or linear topology. Similarly, we assume an OTN is composed of a set of optical cross-connects (OXC) and optical add-drop multiplexer (OADM) which is interconnected in a general mesh topology using DWDM optical line systems (OLS).

treat an
the
and
subnetwork
and a
points.
It is often convenient for easy discussion and description to treat an optical network as a sub-network cloud, in which the details of the network become less important, instead focus is on the function and the interfaces the optical network provides. In general, a subnetwork can be defined as a set of access points on the network boundary and a set of point-to-point optical connections between those access points.

6.2. Control Domains and Interfaces

A generic carrier network reference model describes a multi-

carrier network environment. Each individual carrier network can be further partitioned into sub-networks or administrative domains based on administrative, technological or architectural reasons. This partition can be recursive. Similarly, a network can be partitioned into control domains that match the administrative domains and are controlled by a single administrative policy. The control domains can be recursively divided into sub-domains to form control hierarchy for scalability. The control domain concept can be applied to routing, signaling and protection & restoration to form an autonomous control function domain.

The demarcation between domains can be either logical or physical and consists of a set of reference points identifiable in the optical network. From the control plane perspective, these reference points define a set of control interfaces in terms of optical control and management functionality as illustrated in Figure 1.

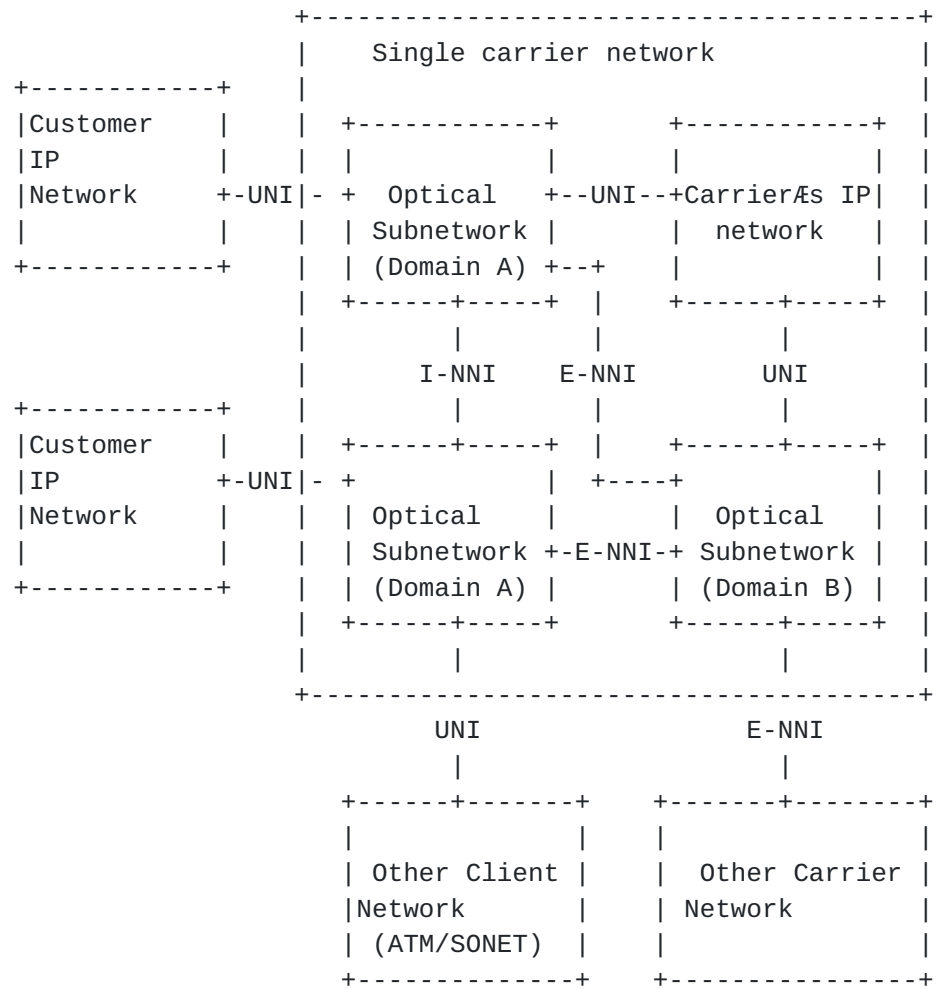

Figure 1 Generic Carrier Network Reference Model

The network interfaces encompass two aspects of the networking functions: user data plane interface and control plane interface.

The

former concerns about user data transmission across the physical network interface and the latter concerns about the control

message

exchange across the network interface such as signaling, routing,

etc.

We call the former physical interface (PI) and the latter control interface (CI). Unless otherwise stated, the CI is assumed in the remaining of this document.

6.2.1. Control Plane Interfaces

connected

The Control Interface defines the relationship between two network entities on both sides of the interface. For each control

side
across
may

interface, we need to define the architectural function that each
plays and a controlled set of information that can be exchanged
the interface. The information flowing over this logical interface
include, but not limited to:
- Interface endpoint name and address

- Reachability/summarized network address information
- Topology/routing information
- Authentication and connection admission control information
- Connection management signaling messages
- Network resource control information

and
points
in the control plane. In this document, the following set of
interfaces is defined as shown in Figure 1.
User-Network Interface (UNI): is a bi-directional control
interface
The
between service requester and service provider control entities.
service request control entity resides outside the carrier network
control domain.

Network-Network/Node-Node Interface (NNI): is a bi-directional
signaling interface between two optical network elements or sub-
networks.

NNI)
We differentiate between internal NNI (I-NNI) and external NNI (E-
as follows:
- E-NNI: A NNI between two control plane entities belonging to
different control domains.
- I-NNI: A NNI between two control plane entities within the same
control domain in the carrier network.

different
purposes.
control
on
Different types of interface, internal vs. external, have
implied trust relationship for security and access control
The trust relationship is not binary. Instead a policy-based
mechanism need to be in place to restrict the type and amount of
information that can flow cross each type of interfaces depending
the carrier's service and business requirements.

control
Generally, two networks have a fully trusted relationship if they
belong to the same administrative domain. In this case, the

information exchanged across the control interface between them
should
be unlimited. Otherwise, the type and amount of the control
information that can go across the information should be
constrained
by the administrative policy.

An example of fully trusted interface is an I-NNI between two
optical
network elements in a single control domain. Non-trusted interface
examples include an E-NNI between two different carriers or a UNI
interface between a carrier optical network and its customers. The
trust level can be different for the non-trusted UNI or E-NNI

general, interface depending upon if it within the carrier or not. In intra-carrier E-NNI has higher trust level than inter-carrier E-NNI.

described The control plane shall support the UNI and NNI interface above and the interfaces shall be configurable in terms of the type and amount of control information exchange and their behavior shall be consistent with the configuration (i.e., external versus internal interfaces).

6.3. Intra-Carrier Network Model

and Intra-carrier network model concerns the network service control management issues within networks owned by a single carrier.

6.3.1. Multiple Sub-networks

optical Without loss of generality, the optical network owned by a carrier service operator can be depicted as consisting of one or more many sub-networks interconnected by direct optical links. There may be the different reasons for more than one optical sub-network. It may be across result of using hierarchical layering, different technologies access, metro and long haul (as discussed below), or a result of business mergers and acquisitions or incremental optical network technology deployment by the carrier using different vendors or technologies.

network. A sub-network may be a single vendor and single technology

But in general, the carrier's optical network is heterogeneous in terms of equipment vendor and the technology utilized in each sub-network.

6.3.2. Access, Metro and Long-haul networks

Even Few carriers have end-to-end ownership of the optical networks.

networks. if they do, access, metro and long-haul networks often belong to different administrative divisions as separate optical sub-

terms
different
network
multiple

Therefore Inter-(sub)-networks interconnection is essential in of supporting the end-to-end optical service provisioning and management. The access, metro and long-haul networks may use technologies and architectures, and as such may have different properties.

In general, end-to-end optical connectivity may easily cross sub-networks with the following possible scenarios:

- Access -- Metro -- Access
- Access - Metro -- Long Haul -- Metro - Access

6.4. Inter-Carrier Network Model

The inter-carrier model focuses on the service and control aspects between different carrier networks and describes the internetworking

relationship between them. The inter-carrier connection is often only constrained technical and business requirements, but by the government regulations as well,

Inter-carrier interconnection provides for connectivity between optical network operators. To provide globally reachable end-to-

optical services, optical service control and management between different carrier networks becomes essential. For example, it is possible to support distributed peering within the IP client layer network where the connectivity between two distant IP routers can

achieved via an inter-carrier optical transport connection.

6.5. Implied Control Constraints

The intra-carrier and inter-carrier models have different implied control constraints. For example, in the intra-carrier model, the address for routing and signaling only need to be unique with the carrier while the inter-carrier model requires the address to be globally unique.

In the intra-carrier network model, the network itself forms the largest control domain within the carrier network. This domain is usually partitioned into multiple sub-domains, either flat or hierarchical. The UNI and E-NNI interfaces are internal to the

network, therefore higher trust level is assumed. Because of this, direct signaling between domains and summarized topology and

information exchanged can be allowed across the internal UNI or carrier E-NNI interfaces.

In the inter-carrier network model, each carrier's optical network is a separate administrative domain. Both the UNI interface between

user and the carrier network and the NNI interface between two carrier's networks are crossing the carrier's administrative

and therefore are external interfaces by definition.

In terms of control information exchange, the topology information shall not be allowed to cross both E-NNI and UNI interfaces.

7. Optical Service User Requirements

reflect This section describes the user requirements for optical services, which in turn impose the requirements on service control and management for the network operators. The user requirements
the perception of the optical service from a user's point of view.

7.1. Common Optical Services

services The basic unit of an optical transport service is fixed-bandwidth optical connectivity between applications. However different
bit are created based on its supported signal characteristics (format,

associated rate, etc), the service invocation methods and possibly the Service Level Agreement (SLA) provided by the service provider.

At present, the following are the major optical services provided in the industry:

- SONET/SDH, with different degrees of transparency
- Optical wavelength services, transparent or opaque
- Ethernet at 10Mbps, 100Mbps, 1 Gbps and 10 Gbps
- Storage Area Networks (SANs) based on Fiber Connectivity (FICON), Enterprise Storage Connectivity (ESCON) and Fiber Channel (FC).

Optical Wavelength Service refers to transport services where signal framing is negotiated between the client and the network operator (framing and bit-rate dependent), and only the payload is carried transparently. SONET/SDH transport is most widely used for network-wide transport. Different levels of transparency can be achieved in the SONET/SDH transmission.

Ethernet Services, specifically 1Gb/s and 10Gbs Ethernet services, are gaining more popularity due to the lower costs of the customers' premises equipment and its simplified management requirements (compared to SONET or SDH).

Ethernet services may be carried over either SONET/SDH (GFP mapping) or WDM networks. The Ethernet service requests will require some service specific parameters: priority class, VLAN ID/Tag, traffic aggregation parameters.

ESCON and FICON are proprietary versions of the SAN service, while Fiber Channel is the standard alternative. As is the case with SDH Ethernet services, SAN services may be carried over either SONET/ (using GFP mapping) or WDM networks.

The control plane shall provide the carrier with the capability listed functionality to provision, control and manage all the services above.

7.2. Bearer Interface Types

All the bearer interfaces implemented in the ONE shall be supported by the control plane and associated signaling protocols.

The signaling shall support the following interface types protocol:

- SDH/SONET
- Ethernet
- FC-N for Fiber Channel services
- OTN (G.709)
- PDH (Plesiosynchronous Digital Hierarchy)

7.3. Optical Service Invocation

As mentioned earlier, the methods of service invocation play an important role in defining different services.

7.3.1. Provider-Initiated Service Provisioning

provider In this scenario, users forward their service request to the
via a well-defined service management interface. All connection management operations, including set-up, release, query, or modification shall be invoked from the management plane. This provisioning method is for PC and SPC connections.

7.3.2. User-Initiated Service Provisioning

provider In this scenario, users forward their service request to the
via a well-defined UNI interface in the control plane (including
proxy signaling). All connection management operation requests,
including set-up, release, query, or modification shall be invoked from
directly connected user devices, or its signaling proxy. This provisioning method is for SC connection.

7.3.3. Call set-up requirements

been In summary the following requirements for the control plane have
identified:
to - The control plane shall support action result codes as responses
any requests over the control interfaces.

subject to - The control plane shall support requests for call set-up,
policies in effect between the user and the network.
- The control plane shall support the destination client device's decision to accept or reject call set-up requests from the source client's device.
- The control plane shall support requests for call set-up and deletion across multiple (sub)networks.

- NNI signaling shall support requests for call set-up, subject to

policies in effect between the (sub)networks.

- Call set-up shall be supported for both uni-directional and bi-directional connections.

- Upon call request initiation, the control plane shall generate a network unique Call-ID associated with the connection, to be used

for

information retrieval or other activities related to that

connection.

- It shall be provided as part of the call control functionality.
- is the role of the CAC function to determine if the call can be allowed to proceed based on resource availability and authentication.
- shall be supported.
- setup requests can be authorized.
- pace) call setup attempts into the network.
- report to the management plane shall report to the management plane, the success/failures of a call request.
- shall be the management plane a cause code identifying the reason for the failure and all allocated resources shall be released. A negative acknowledgment shall be returned to the source.
- Call- ID.
- node to initiate call release procedures.
- call shall become available for access for new requests.
- connections established by the control plane both gracefully and forcibly on demand.
- Partially deleted calls or connections shall not remain within

the

network.

- End-to-end acknowledgments shall be used for connection deletion requests.
- Connection deletion shall not result in either restoration or protection being initiated.
- The control plane shall support management plane and neighboring device requests for status query.

client - The UNI shall support initial registration and updates of the
with the network via the control plane.

7.4. Optical Connection granularity

the The service granularity is determined by the specific technology,
framing and bit rate of the physical interface between the ONE and
client at the edge and by the capabilities of the ONE. The control
plane needs to support signaling and routing for all the services
supported by the ONE. In general, there should not be a one-to-one
provided correspondence imposed between the granularity of the service
and the maximum capacity of the interface to the user.

The control plane shall support the ITU Rec. G.709 connection
granularity for the OTN network.

granularity. The control plane shall support the SDH/SONET connection

as VT The optical control plane shall support sub-rate interfaces such
/TU granularity (as low as 1.5 Mb/s).

equipment: The following fiber channel interfaces shall be supported by the
control plane if the given interfaces are available on the

- FC-12
- FC-50
- FC-100
- FC-200

new Encoding of service types in the protocols used shall be such that
objects. service types can be added by adding new code point values or

7.5. Other Service Parameters and Requirements

7.5.1 Classes of Service

characteristics of We use "service level" to describe priority related
connections, such as holding priority, set-up priority, or
restoration priority. The intent currently is to allow each carrier to define
the

restoration actual service level in terms of priority, protection, and options. Therefore, individual carriers will determine mapping of individual service levels to a specific set of quality features.

options. The control plane shall be capable of mapping individual service classes into specific priority or protection and restoration

7.5.2. Diverse Routing Attributes

resources Diversity refers to the fact that a disjoint set of network (links and nodes) is utilized to provision multiple parallel optical connections terminated between a pair of ingress and egress ports.

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 20]

There are different levels of diversity based on link, node or administrative policy as described below. In the simple node and

link

diversity case:

the

- Two optical connections are said to be node-disjoint diverse, if two connections do not share any node along the path except the ingress and egress nodes.

the

- Two optical connections are said to be link-disjoint diverse, if two connections do not share any link along the path.

group of

can

group.

A more general concept of diversity is the Shared Risk Group (SRG) that is based on a risk-sharing model and allows the definition of administrative policy-based diversity. A SRG is defined as a

links or nodes that share a common risk component, whose failure potentially cause the failure of all the links or nodes in the

go

When the SRG is applied to the link resource, it is referred to as shared risk link group (SRLG). For example, all fiber links that

failure,

that

through a common conduit under the ground belong to the same SRLG group, because the conduit is a shared risk component whose

such as a cut, may cause all fibers in the conduit to break. Note

technical or

miles

SRLG is a relation defined within a group of links based upon a specific risk factor that can be defined based on various

administrative grounds such as "sharing a conduit", "within 10

of distance proximity" etc. Please see ITU-T G.7715 for more discussion [[itu-rtg](#)].

diverse

to

Therefore, two optical connections are said to be SRG-disjoint

if the two connections do not have any links or nodes that belong

the same SRG along the path.

is

The ability to route service paths diversely is a required control feature. Diverse routing is one of the connection parameters and

specified at the time of the connection creation.

optical

The control plane routing algorithms shall be able to route an

of connection diversely from a previously routed connection in terms
link disjoint path, node disjoint path and SRG disjoint path.

8. Optical Service Provider Requirements

This section discusses specific service control and management requirements from the service provider's point of view.

8.1. Service Access Methods to Optical Networks

on In order to have access to the optical network service, a customer
needs to be physically connected to the service provider network
be the transport plane. The control plane connection may or may not
the required depending upon the service invocation model provided to
customer: provisioned vs. signaled. For the signaled, either
direct or indirect signaling methods can be used depending upon if the UNI
proxy

is utilized on the client side. The detailed discussion on the UNI signaling methods is in [[oif-uni](#)].

Multiple access methods shall be supported:

- Cross-office access (CNE co-located with ONE)
- Direct remote access (Dedicated links to the user)
- Remote access via access sub-network (via a multiplexing/distribution sub-network)

8.2. Dual Homing and Network Interconnections

devices
different
connectivity
use

Dual homing is a special case of the access network. Client can be dual homed to the same or different hub, the same or access network, the same or different core networks, the same or different carriers. The different levels of dual homing result in many different combinations of configurations. The main objective for dual homing is for enhanced survivability.

Dual homing must be supported. Dual homing shall not require the use of multiple addresses for the same client device.

8.3. Inter-domain connectivity

discusses

A domain is a portion of a network, or an entire network that is controlled by a single control plane entity. This section the various requirements for connecting domains.

8.3.1. Multi-Level Hierarchy

inter-
access
different
through

Traditionally current transport networks are divided into core city long haul networks, regional intra-city metro networks and networks. Due to the differences in transmission technologies, service, and multiplexing needs, the three types of networks are served by different types of network elements and often have capabilities. The network hierarchy is usually implemented the control domain hierarchy.

When control domains exists for routing and signaling purpose,

there

will be intra-domain routing/signaling and inter-domain routing/signaling. In general, domain-based routing/signaling

autonomy

is desired and the intra-domain routing/signaling and the inter-

domain

routing/signaling should be agnostic to each other.

supported

Routing and signaling for multi-level hierarchies shall be

to allow carriers to configure their networks as needed.

8.3.2. Network Interconnections

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 22]

Sub-networks may have multiple points of inter-connections. All relevant NNI functions, such as routing, reachability information exchanges, and inter-connection topology discovery must recognize

and

support multiple points of inter-connections between subnetworks.

Dual

inter-connection is often used as a survivable architecture.

for

The control plane shall provide support for routing and signaling subnetworks having multiple points of interconnection.

8.4. Names and Address Management

8.4.1. Address Space Separation

To ensure the scalability of and smooth migration toward to the optical switched network, the separation of three address spaces

are

required as discussed in [[oif-addr](#)]:

if

- Internal transport network addresses: This is used for routing control plane messages within the transport network. For example,

GMPLS is used then IP address should be used.

address

- Transport Network Assigned (TNA) address: This is a routable in the optical transport network and is assigned by the network.

layer.

- Client addresses: This address has significance in the client

be

For example, if the clients are ATM switches, the NSAP address can be used. If the clients are IP router, then IP address should be

used.

8.4.2. Directory Services

translation

Directory Services shall support address resolution and

schemes

between various user/client device names or address and the corresponding TNA addresses. UNI shall use the user naming

for connection request. The directory service is essential for the implementation of overlay model.

8.4.3. Network element Identification

network

Each control domain and each network element within a carrier shall be uniquely identifiable. Similarly all the service access points shall be uniquely identifiable.

8.5. Policy-Based Service Management Framework

The optical service must be supported by a robust policy-based management system to be able to make important decisions.

Examples of policy decisions include:

- What types of connections can be set up for a given UNI?

- What information can be shared and what information must be restricted in automatic discovery functions?
- What are the security policies over signaling interfaces?
- What routing policies should be applied in the path selection?

E.g

The definition of the link diversity.

Requirements:

- Service and network policies related to configuration and provisioning, admission control, and support of Service Level Agreements (SLAs) must be flexible, and at the same time simple

and

scalable.

standards-

- The policy-based management framework must be based on based policy systems (e.g., IETF COPS [[rfc2784](#)]).

be

- In addition, the IPO service management system must support and backwards compatible with legacy service management systems.

plane

9. Control Plane Functional Requirements for Optical Services
This section addresses the requirements for the optical control in support of service provisioning.

interfaces

The scope of the control plane includes the control of the and network resources within an optical network and the interfaces between the optical network and its client networks. In other

words,

it should include both NNI and UNI aspects.

9.1. Control Plane Capabilities and Functions

The control capabilities are supported by the underlying control functions and protocols built in the control plane.

9.1.1. Network Control Capabilities

plane

The following capabilities are required in the network control to successfully deliver automated provisioning for optical

services:

- Network resource discovery
- Address assignment and resolution

- Routing information propagation and dissemination
- Path calculation and selection
- Connection management

These capabilities may be supported by a combination of functions across the control and the management planes.

9.1.2. Control Plane Functions for Network Control

The following are essential functions needed to support network control capabilities:

- Signaling
- Routing
- Automatic resource, service and neighbor discovery

Specific requirements for signaling, routing and discovery are addressed in [Section 10](#).

The general requirements for the control plane functions to support optical networking and service functions include:

- The control plane must have the capability to establish, teardown and maintain the end-to-end connection, and the hop-by-hop connection segments between any two end-points.
- The control plane must have the capability to support optical traffic-engineering (e.g. wavelength management) requirements including resource discovery and dissemination, constraint-based routing and path computation.
- The control plane shall support network status or action result code responses to any requests over the control interfaces.
- The control plane shall support call admission control on UNI and connection-admission control on NNI.
- The control plane shall support graceful release of network resources associated with the connection after a successful connection teardown or failed connection.
- The control plane shall support management plane request for connection attributes/status query.
- The control plane must have the capability to support various protection and restoration schemes.
- Control plane failures shall not affect active connections and shall not adversely impact the transport and data planes.
- The control plane should support separation of control function

allow entities including routing, signaling and discovery and should
including different control distributions of those functionalities,
centralized, distributed or hybrid.

control - The control plane should support physical separation of the
or plane from the transport plane to support either tightly coupled
loosely coupled control plane solutions.

- The control plane should support the routing and signaling proxy to participate in the normal routing and signaling message exchange and processing.

- Resilience and security are crucial issues for the control plane and will be addressed in [Section 11](#) and 12 of this document respectively.

9.2. Signaling Communication Network (SCN)

The signaling communication network is a transport network for control plane messages and it consists of a set of control channels that interconnects the nodes within the control plane. Therefore, the signaling communication network must be accessible by each of the communicating nodes (e.g., OXCs). If an out-of-band IP-based control message transport network is an overlay network built on top of the IP data network using some tunneling technologies, these tunnels must be standards-based such as IPSec, GRE, etc.

- The signaling communication network must terminate at each of the nodes in the transport plane.

- The signaling communication network shall not be assumed to have the same topology as the data plane, nor shall the data plane and control plane traffic be assumed to be congruently routed.

A control channel is the communication path for transporting control messages between network nodes, and over the UNI (i.e., between the UNI entity on the user side and the UNI entity on the network side).

The control messages include signaling messages, routing information messages, and other control maintenance protocol messages such as neighbor and service discovery.

The following three types of signaling in the control channel shall be

supported:

logical
or
framing
signaling

- In-band signaling: The signaling messages are carried over a communication channel embedded in the data-carrying optical link channel. For example, using the overhead bytes in SONET data as a logical communication channel falls into the in-band methods.

carried
data-
dedicated

- In fiber, Out-of-band signaling: The signaling messages are over a dedicated communication channel separate from the optical bearing channels, but within the same fiber. For example, a wavelength or TDM channel may be used within the same fiber as the data channels.

a

- Out-of-fiber signaling: The signaling messages are carried over dedicated communication channel or path within different fibers to those used by the optical data-bearing channels. For example, dedicated optical fiber links or communication path via separate

and

independent IP-based network infrastructure are both classified as out-of-fiber signaling.

1.0

The UNI control channel and proxy signaling defined in the OIF UNI

[[oif-uni](#)] shall be supported.

mechanisms

The signaling communication network provides communication between entities in the control plane.

message

- The signaling communication network shall support reliable transfer.

- The signaling communication network shall have its own OAM mechanisms.

support

- The signaling communication network shall use protocols that congestion control mechanisms.

over

In addition, the signaling communication network should support message priorities. Message prioritization allows time critical messages, such as those used for restoration, to have priority

other messages, such as other connection signaling messages and topology and resource discovery messages.

The signaling communication network shall be highly reliable and implement failure recovery.

9.3 Control Plane Interface to Data Plane

decoupled,

In the situation where the control plane and data plane are

standard

this interface needs to be standardized. Requirements for a

a

control-data plane interface are under study. The specification of

this

control plane interface to the data plane is outside the scope of document.

configure

Control plane should support a standards based interface to

switching fabrics and port functions via the management plane.

and

Data plane shall monitor and detect the failure (LOL, LOS, etc.)

plane
plane.
quality degradation (high BER, etc.) of the signals and be able to
provide signal-failure and signal-degrade alarms to the control
accordingly to trigger proper mitigation actions in the control

9.4. Management Plane Interface to Data Plane

of
The management plane shall be responsible for the network resource
management in the data plane. It should be able to partition the
network resources and control the allocation and the deallocation
the resource for use by the control plane.

Data plane shall monitor and detect the failure and quality degradation of the signals and be able to provide signal-failure

and

signal-degrade alarms plus associated detailed fault information

to

the management plane to trigger and enable the management for

fault

location and repair.

Management plane failures shall not affect the normal operation of

a

configured and operational control plane or data plane.

9.5. Control Plane Interface to Management Plane

The control plane is considered a managed entity within a network. Therefore, it is subject to management requirements just as other managed entities in the network are subject to such requirements.

The control plane should be able to service the requests from the management plane for end-to-end connection provisioning (e.g. SPC connection) and control plane database information query (e.g. topology database)

The control plane shall report all control plane faults to the management plane with detailed fault information

defined

The control, management and transport plane each has its well-

network functions. Those functions are orthogonal to each other.

management

However, this does not imply total independency. Since the

plane is responsible for the management of both control plane and transport plane, the management plane plays an authoritative role

control

In general, the management plane shall have authority over the

plane. Management plane should be able to configure the routing, signaling and discovery control parameters such as hold-down

timers,

hello-interval, etc. to affect the behavior of the control plane.

In the case of network failure, both the management plane and the control plane need fault information at the same priority. The

control

plane shall be responsible for providing necessary statistic data

such

as call counts and traffic stats to the management plane. They

should

be available upon query from the management plane. The management plane shall be able to tear down connections established by the control plane both gracefully and forcibly on demand.

9.6. IP and Optical Control Plane Interconnection

The control plane interconnection model defines how two control networks can be interconnected in terms of controlling relationship and control information flow allowed between them. There are three basic types of control plane network interconnection models: overlay, peer and hybrid, which are defined in the IETF IPO WG document [ipo-frame]. See [Appendix A](#) for more discussion.

Choosing the level of coupling depends upon a number of different factors, some of which are:

- Variety of clients using the optical network
- Relationship between the client and optical network
- Operating model of the carrier

Overlay model (UNI like model) shall be supported for client to optical control plane interconnection.

Other models are optional for client to optical control plane interconnection.

models
For optical to optical control plane interconnection all three shall be supported. In general, the priority for support of interconnection models should be overlay, hybrid and peer, in decreasing order.

10. Requirements for Signaling, Routing and Discovery

NNI
10.1. Requirements for information sharing over UNI, I-NNI and E-

and
Different types of interfaces shall impose different requirements functionality due to their different trust relationships. Specifically:

- carrier E-
and
- Topology information shall not be exchanged across inter- NNI and UNI.
 - The control plane shall allow the carrier to configure the type extent of control information exchange across various interfaces.
 - Address resolution exchange over UNI is needed if an addressing directory service is not available.

10.2. Signaling Functions

used
an
word
Call and connection control and management signaling messages are for the establishment, modification, status query and release of end-to-end optical connection. Unless otherwise specified, the "signaling" refers to both inter-domain and intra-domain

signaling.

intra-

connection

- The inter-domain signaling protocol shall be agnostic to the domain signaling protocol for all the domains within the network.
- Signaling shall support both strict and loose routing.
- Signaling shall support individual as well as groups of requests.
- Signaling shall support fault notifications.

- Inter-domain signaling shall support per connection, globally unique identifiers for all connection management primitives based on a well-defined naming scheme.
- Inter-domain signaling shall support crank-back and rerouting.

10.3. Routing Functions

Routing includes reachability information propagation, network topology/resource information dissemination and path computation. Network topology/resource information dissemination is to provide

each node in the network with information about the carrier network

such

that a single node is able to support constraint-based path

selection.

A mixture of hop-by-hop routing, explicit/source routing and hierarchical routing will likely be used within future transport networks.

All three mechanisms (Hop-by-hop routing, explicit / source-based routing and hierarchical routing) must be supported. Messages crossing untrusted boundaries must not contain information

regarding

the details of an internal network topology.

Requirements for routing information dissemination:

intra-

- The inter-domain routing protocol shall be agnostic to the

network.

domain routing protocol within any of the domains within the

- The exchange of the following types of information shall be supported by inter-domain routing protocols:

- Inter-domain topology
- Per-domain topology abstraction
- Per domain reachability summarization

and

Major concerns for routing protocol performance are scalability

stability, which impose the following requirement on the routing protocols:

- The routing protocol shall scale with the size of the network

The routing protocols shall support following requirements:

- Routing protocol shall support hierarchical routing information

dissemination, including topology information aggregation and summarization.

keep
service
related

- The routing protocol(s) shall minimize global information and information locally significant as much as possible. Over external interfaces only reachability information, next routing hop and capability information should be exchanged. Any other network information shall not leak out to other networks.

information (e.g., ports individually. information shall

- The routing protocol shall be able to minimize global and keep information locally significant as much as possible information local to a node, a sub-network, a domain, etc). For example, a single optical node may have thousands of ports. The with common characteristics need not to be advertised
- The routing protocol shall distinguish static routing and dynamic routing information. The routing protocol operation update dynamic and static routing information differently. Only dynamic routing information shall be updated in real time.
- Routing protocol shall be able to control the dynamic updating frequency through different types of thresholds. Two thresholds could be defined: absolute threshold and relative threshold.
- The routing protocol shall support trigger-based and timeout-based information update.
- Inter-domain routing protocol shall support policy-based routing information exchange.
- The routing protocol shall be able to support different levels of protection/restoration and other resiliency requirements. These are discussed in [Section 11](#).

routing

All the scalability techniques will impact the network resource representation accuracy. The tradeoff between accuracy of the information and the routing protocol scalability is an important consideration to be made by network operators.

10.4. Requirements for path selection

The following are functional requirements for path selection:

- Path selection shall support shortest path routing.
- Path selection shall also support constraint-based routing. At least

the following constraints shall be supported:

- Cost
 - Link utilization
 - Diversity
 - Service Class
- Path selection shall be able to include/exclude some specific network resources, based on policy.
- Path selection shall be able to support different levels of diversity, including node, link, SRLG and SRG.
- Path selection algorithms shall provide carriers the ability to support a wide range of services and multiple levels of service

classes. Parameters such as service type, transparency, bandwidth, latency, bit error rate, etc. may be relevant.

Constraint-based routing in the optical network is significantly complex compared to the IP network. There are many optical layer constraints to consider such as wavelength, diversity, optical

layer

impairments, etc. A detailed discussion on the routing

constraints at

the optical layer is in [ietf-olr].

10.5. Discovery Functions

The discovery functions include neighbor, resource and service discovery. The control plane shall support both manual

configuration

and automatic discovery

10.5.1. Neighbor discovery

Neighbor Discovery can be described as an instance of auto-

discovery

that is used for associating two network entities within a layer network based on a specified adjacency relation.

The control plane shall support the following neighbor discovery capabilities as described in [itu-disc]:

- Physical media adjacency that detects and verifies the physical layer network connectivity between two connected network element ports.

- Logical network adjacency that detects and verifies the logical network layer connection above the physical layer between network layer specific ports.

- Control adjacency that detects and verifies the logical

neighboring

relation between two control entities associated with data plane network elements that form either physical or logical adjacency.

The control plane shall support manual neighbor adjacency configuration to either overwrite or supplement the automatic

neighbor

discovery function.

10.5.2. Resource Discovery

Resource discovery is concerned with the ability to verify

physical

connectivity between two ports on adjacent network elements,

improve

inventory management of network resources, detect configuration

mismatches between adjacent ports, associating port characteristics of adjacent network elements, etc. Resource discovery shall be supported.

Resource discovery can be achieved through either manual provisioning or automated procedures. The procedures are generic while the specific mechanisms and control information can be technology dependent.

must be After neighbor discovery, resource verification and monitoring performed periodically to verify physical attributes to ensure compatibility.

10.5.3. Service Discovery

discovery Service Discovery can be described as an instance of auto-
a that is used for verifying and exchanging service capabilities of
discovery. network. Service discovery can only happen after neighbor
discovery. Since service capabilities of a network can dynamically change, service discovery may need to be repeated. Service discovery is required for all the optical services supported.

11. Requirements for service and control plane resiliency

under Resiliency is a network capability to continue its operations
switched the condition of failures within the network. The automatic
those optical network assumes the separation of control plane and data
data plane. Therefore the failures in the network can be divided into
failure- affecting the data plane and those affecting the control plane. To
provide enhanced optical services, resiliency measures in both
plane and control plane should be implemented. The following
handling principles shall be supported.

and The control plane shall provide optical service failure detection
the recovery functions such that the failures in the data plane within
control plane coverage can be quickly mitigated.

the The failure of control plane shall not in any way adversely affect
plane. normal functioning of existing optical connections in the data

major In general, there shall be no single point of failure for all
control control plane functions, including signaling, routing etc. The
plane shall provide reliable transfer of signaling messages and

flow
plane.

control mechanisms for easing any congestion within the control

11.1. Service resiliency

reliability of
the
the
switch

In circuit-switched transport networks, the quality and
the established optical connections in the transport plane can be
enhanced by the protection and restoration mechanisms provided by
control plane functions. Rapid recovery is required by transport
network providers to protect service and also to support stringent
Service Level Agreements (SLAs) that dictate high reliability and
availability for customer connectivity.

the
switch

The protection and restoration actions are usually in reaction to
failure in the networks. However, during the network maintenance
affecting the protected connections, a network operator needs to
proactively force the traffic on the protected connections to
to its protection connection. Therefore in order to support easy

network maintenance, it is required that management initiated protection and restoration be supported.

usually
by
The failure and signal degradation in the transport plane is technology specific and therefore shall be monitored and detected the transport plane.

The transport plane shall report both physical level failure and signal degradation to the control plane in the form of the signal failure alarm and signal degrade alarm.

failure
The control plane shall support both alarm-triggered and hold-down timers based protection switching and dynamic restoration for recovery.

availability.
level",
options
restoration
a
carriers
Clients will have different requirements for connection. These requirements can be expressed in terms of the "service level", which can be mapped to different restoration and protection and priority related connection characteristics, such as holding priority (e.g. pre-emptable or not), set-up priority, or priority. However, how the mapping of individual service levels to a specific set of protection/restoration options and individual carriers will determine connection priorities.

the
In order for the network to support multiple grades of service, control plane must support differing protection and restoration options on a per connection basis.

the
and
In order for the network to support multiple grades of service, control plane must support setup priority, restoration priority holding priority on a per connection basis.

for
In general, the following protection schemes shall be considered all protection cases within the network:
- Dedicated protection: 1+1 and 1:1
- Shared protection: 1:N and M:N.

- Unprotected

The control plane shall support "extra-traffic" capability, which allows unprotected traffic to be transmitted on the protection circuit.

The control plane shall support both trunk-side and drop-side protection switching.

The following restoration schemes should be supported:

- Restorable
- Un-restorable

end

Protection and restoration shall be supported on both an end-to-basis and a link-by-link basis.

software Protection and restoration configuration should be based on only.

The control plane shall allow the modification of protection and restoration attributes on a per-connection basis.
The control plane shall support mechanisms for reserving bandwidth resources for restoration.

connection The control plane shall support mechanisms for normalizing routing (reversion) after failure repair.

deletion) Normal connection management operations (e.g., connection shall not result in protection/restoration being initiated.

11.2. Control plane resiliency

and The control plane may be affected by failures in signaling network connectivity and by software failures (e.g., signaling, topology resource discovery modules).

The control plane should implement signaling message priorities to ensure that restoration messages receive preferential treatment, resulting in faster restoration.

protection The optical control plane signaling network shall support and restoration options to enable it to be self-healing in case of failures within the control plane.

between Control network failure detection mechanisms shall distinguish control channel and software process failures.

The control plane failure shall only impact the capability to provision new services.

Fault localization techniques for the isolation of failed control resources shall be supported.

recovery Recovery from control plane failures shall result in complete and re-synchronization of the network.

There shall not be a single point of failure in the control plane systems design.

Partial or total failure of the control plane shall not affect the
existing established connections. It should only lose the
capability
to accept the new connection requests.

12. Security Considerations

optical

In this section, security considerations and requirements for services and associated control plane requirements are described.

12.1. Optical Network Security Concerns

stringent

Since optical service is directly related to the physical network, which is fundamental to a telecommunications infrastructure, security assurance mechanism should be implemented in optical networks.

aspects.

In terms of security, an optical connection consists of two

itself

One is security of the data plane where an optical connection belongs, and the other is security of the control plane.

12.1.1. Data Plane Security

data, it

encryption

- Misconnection shall be avoided in order to keep the user's data confidential. For enhancing integrity and confidentiality of data, it may be helpful to support scrambling of data at layer 2 or encryption of data at a higher layer.

12.1.2. Control Plane Security

It is desirable to decouple the control plane from the data plane physically.

short

Restoration shall not result in miss-connections (connections established to a destination other than that intended), even for

should

periods of time (e.g., during contention resolution). For example, signaling messages, used to restore connectivity after failure, should not be forwarded by a node before contention has been resolved.

with

Additional security mechanisms should be provided to guard against intrusions on the signaling network. Some of these may be done

information

the help of the management plane.

- Network information shall not be advertised across external interfaces (UNI or E-NNI). The advertisement of network

information across the E-NNI shall be controlled and limited in a configurable

shall policy based fashion. The advertisement of network information be isolated and managed separately by each administration.

- The signaling network itself shall be secure, blocking all unauthorized access. The signaling network topology and addresses shall not be advertised outside a carrier's domain of trust.
- Identification, authentication and access control shall be rigorously used by network operators for providing access to the control plane.

- Discovery information, including neighbor discovery, service discovery, resource discovery and reachability information should be exchanged in a secure way.

- Information on security-relevant events occurring in the control plane or security-relevant operations performed or attempted in the control plane shall be logged in the management plane.

- The management plane shall be able to analyze and exploit logged data in order to check if they violate or threat security of the control plane.

- The control plane shall be able to generate alarm notifications about security related events to the management plane in an adjustable and selectable fashion.

- The control plane shall support recovery from successful and attempted intrusion attacks.

12.2. Service Access Control

From a security perspective, network resources should be protected from unauthorized accesses and should not be used by unauthorized entities. Service access control is the mechanism that limits and controls entities trying to access network resources. Especially

the UNI and E-NNI, Connection Admission Control (CAC) functions

should also support the following security features:

- CAC should be applied to any entity that tries to access network resources through the UNI (or E-NNI). CAC should include an authentication function of an entity in order to prevent

masquerade (spoofing). Masquerade is fraudulent use of network resources by pretending to be a different entity. An authenticated entity

should be given a service access level on a configurable policy basis.

- The UNI and NNI should provide optional mechanisms to ensure authentication and message integrity for connection management requests such as set-up, tear-down and modify and connection

signaling messages. This is important in order to prevent Denial of Service attacks. The UNI and E-NNI should also include mechanisms, such as usage-based billing based on CAC, to ensure non-repudiation of

connection management messages.

according

- Each entity should be authorized to use network resources to the administrative policy set by the operator.

[Appendix A](#): Interconnection of Control Planes

The interconnection of the IP router (client) and optical control planes can be realized in a number of ways depending on the required level of coupling. The control planes can be loosely or tightly coupled. Loose coupling is generally referred to as the overlay model and tight coupling is referred to as the peer model. Additionally there is the augmented model that is somewhat in between the other two models but more akin to the peer model. The model selected determines the following:

- The details of the topology, resource and reachability information advertised between the client and optical networks
- The level of control IP routers can exercise in selecting paths across the optical network

The next three sections discuss these models in more details and the last section describes the coupling requirements from a carrier's

perspective.

Peer Model (I-NNI like model)

Under the peer model, the IP router clients act as peers of the optical transport network, such that single routing protocol

instance

optical

the

runs over both the IP and optical domains. In this regard the network elements are treated just like any other router as far as

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 40]

control plane is concerned. The peer model, although not strictly an internal NNI, behaves like an I-NNI in the sense that there is sharing of resource and topology information.

Presumably a common IGP such as OSPF or IS-IS, with appropriate extensions, will be used to distribute topology information. One tacit assumption here is that a common addressing scheme will also be used for the optical and IP networks. A common address space can be trivially realized by using IP addresses in both IP and optical domains. Thus, the optical networks elements become IP addressable entities.

The obvious advantage of the peer model is the seamless interconnection between the client and optical transport networks. The tradeoff is that the tight integration and the optical specific routing information that must be known to the IP clients.

The discussion above has focused on the client to optical control plane inter-connection. The discussion applies equally well to connecting two optical control planes.

Overlay (UNI-like model)

Under the overlay model, the IP client routing, topology distribution, and signaling protocols are independent of the routing, topology distribution, and signaling protocols at the optical layer. This model is conceptually similar to the classical IP over ATM model, but applied to an optical sub-network directly.

Though the overlay model dictates that the client and optical network are independent this still allows the optical network to re-use IP layer protocols to perform the routing and signaling functions.

In addition to the protocols being independent the addressing scheme used between the client and optical network must be independent in the overlay model. That is, the use of IP layer addressing in the clients

must not place any specific requirement upon the addressing used within the optical control plane.

through
The overlay model would provide a UNI to the client networks
which the clients could request to add, delete or modify optical connections. The optical network would additionally provide reachability information to the clients but no topology
information
would be provided across the UNI.

Augmented model (E-NNI like model)

Under the augmented model, there are actually separate routing instances in the IP and optical domains, but information from one routing instance is passed through the other routing instance.
For
example, external IP addresses could be carried within the optical

[draft-ietf-ipo-carrier-requirements-05.txt](#)

[page 41]

to IP
client
routing protocols to allow reachability information to be passed
clients. A typical implementation would use BGP between the IP
and optical network.

behaves
The augmented model, although not strictly an external NNI,
like an E-NNI in that there is limited sharing of information.

drive
non-
Generally in a carrier environment there will be more than just IP
routers connected to the optical network. Some other examples of
clients could be ATM switches or SONET ADM equipment. This may

the decision towards loose coupling to prevent undue burdens upon
IP router clients. Also, loose coupling would ensure that future
clients are not hampered by legacy technologies.

just
Additionally, a carrier may for business reasons want a separation
between the client and optical networks. For example, the ISP
business unit may not want to be tightly coupled with the optical
network business unit. Another reason for separation might be

same
pure politics that play out in a large carrier. That is, it would
seem unlikely to force the optical transport network to run that

same
set of protocols as the IP router networks. Also, by forcing the
set of protocols in both networks the evolution of the networks is
directly tied together. That is, it would seem you could not

upgrade
versa).
the optical transport network protocols without taking into
consideration the impact on the IP router network (and vice

coupling.
Operating models also play a role in deciding the level of

including
Four main operating models envisioned for an optical transport
network:

Category 1: ISP owning all of its own infrastructure (i.e.

fiber and duct to the customer premises)

Category 2: ISP leasing some or all of its capacity from a third
party

Category 3: Carriers carrier providing layer 1 services

Category 4: Service provider offering multiple layer 1, 2, and 3 services over a common infrastructure

would
other

Although relatively few, if any, ISPs fall into category 1 it seems the mostly likely of the four to use the peer model. The operating models would lend themselves more likely to choose an overlay model. Most carriers would fall into category 4 and thus would most likely choose an overlay model architecture.
