## Internet Printing Protocol/1.0: Protocol Specification draft-ietf-ipp-protocol-02.txt

Status of this Memo

This document is an Internet-Draft. Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress".

To learn the current status of any Internet-Draft, please check the "1id-abstracts.txt" listing contained in the Internet-Drafts Shadow Directories on ftp.is.co.za (Africa), nic.nordu.net (Europe), munnari.oz.au (Pacific Rim), ds.internic.net (US East Coast), or ftp.isi.edu (US West Coast).

#### Abstract

This document is one of a set of documents, which together describe all aspects of a new Internet Printing Protocol (IPP). IPP is an application level protocol that can be used for distributed printing using Internet tools and technology. The protocol is heavily influenced by the printing model introduced in the Document Printing Application (ISO/IEC 10175 DPA) standard [dpa]. Although DPA specifies both end user and administrative features, IPP version 1.0 is focused only on end user functionality.

The full set of IPP documents includes:

Internet Printing Protocol: Requirements Internet Printing Protocol/1.0: Model and Semantics Internet Printing Protocol/1.0: Protocol Specification

The requirements document takes a broad look at distributed printing

functionality, and it enumerates real-life scenarios that help to clarify the features that need to be included in a printing protocol for the Internet. It identifies requirements for three types of users: end users, operators, and administrators. The requirements document calls out a subset of end user requirements that MUST be satisfied in the Herriot, Butler, October 23, 1997, [Page 1] Moore and Turner

Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

first version of IPP. Operator and administrator requirements are out of scope for v1.0. The model and semantics document describes a simplified model with abstract objects, their attributes, and their operations. The model introduces a Printer object and a Job object. The Job object supports multiple documents per job. The protocol specification is formal document which incorporates the ideas in all the other documents into a concrete mapping using clearly defined data representations and transport protocol mappings that real implementers can use to develop interoperable client and printer (server) side components.

This document is the ''Internet Printing Protocol/1.0: Protocol Specification'' document.

Notice

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

## **1**. Introduction

This document contains the rules for encoding IPP operations and describes two layers: the transport layer and the operation layer.

The transport layer consists of an HTTP/1.1 request or response. RFC <u>2068</u> [r2068] describes HTTP/1.1. This document specifies the HTTP headers that an IPP implementation supports.

The operation layer consists of a message body in an HTTP request or response. The document "Internet Printing Protocol/1.0: Model and Semantics" [ipp-m] defines the semantics of such a message body and the supported values. This document specifies the encoding of an IPP operation. The aforementioned document [ipp-m] is henceforth referred to as the "IPP model document"

#### **2**. Conformance Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>RFC 2119</u> [<u>r2119</u>].

## 3. Encoding of the Operation Layer

The operation layer SHALL contain a single operation request or operation response.

The encoding consists of octets as the most primitive type. There are several types built from octets, but two important types are integers and characters, on which most other data types are built. Every character in this encoding SHALL be a member of the UCS-2 coded character set and SHALL be encoded using UTF-8 which uses 1 to 3 octets per character. Every integer in this encoding SHALL be encoded as a signed integer using two's-complement binary encoding with big-endian format (also known as "network order" and "most significant byte first"). The number of octets for an integer SHALL be 1, 2 or 4, depending on usage in the protocol. Such one-octet integers, henceforth called SIGNED-BYTE, are used for the version and tag fields. Such twobyte integers, henceforth called SIGNED-SHORT are used for the operation, status-code and length fields. Four byte integers, henceforth called SIGNED-INTEGER, are used for values fields.

The following two sections present the operation layer in two ways

- . informally through pictures and description
- . formally through Augmented Backus-Naur Form (ABNF), as specified by draft-ietf-drums-abnf-02.txt [abnf]

Herriot, Butler, October 23, 1997, [Page 4]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

#### 3.1 Picture of the Encoding

The encoding for an operation request or response consists of:

-----2 bytes - required version -----|operation (request) or status-code (response)| 2 bytes - required \_\_\_\_\_ | xxx-attributes-tag 1 byte | -----|-0 or more xxx-attribute-sequence | n bytes | \_\_\_\_\_ 1 byte - required data-tag \_\_\_\_\_ data | q bytes - optional -----

The xxx-attributes-tag and xxx-attribute-sequence represents four different values of "xxx", namely, operation, job, printer and unsupported-job. The xxx-attributes-tag and xxx-attribute-sequence may be omitted if the operation has no attributes or it may be repeated with the same or different values of "xxx" in ways that are specific to each operation. The data is omitted from some operations, but the data-tag is present even when the data is omitted. Note, the xxx-attributestags and data-tag are called `delimiter-tags'.

Note: the xxx-attribute-sequence, shown above may consist of 0 bytes, according to the rule below.

An xxx-attributes-sequence consists of zero or more compound-attributes.

| compound-attribute | s bytes - 0 or more

A compound-attribute consists an attribute with a single value followed by zero or more additional values.

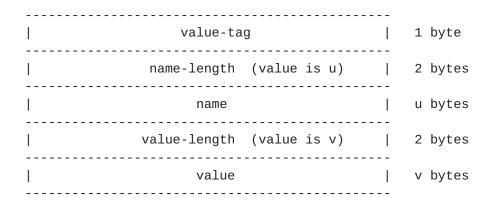

Note: a `compound-attribute' represents a single attribute in the model document. The `additional value' syntax is for attributes with 2 or more values.

Each attribute consists of:

Herriot, Butler,October 23, 1997,[Page 5]

#### Moore and Turner

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

An additional value consists of:

				· _
	value-tag	Ι	1 byte	1
	name-length (value is 0x0000)		2 bytes	  -0 or more
	value-length (value is w)		2 bytes	
	value		w bytes	

Note: an additional value is like an attribute whose name-length is 0. From the standpoint of a parsing loop, the encoding consists of:

-----2 bytes - required version |operation (request) or status-code (response)| 2 bytes - required tag (delimiter-tag or value-tag) | 1 byte | -----|-0 or more empty or rest of attribute | x bytes | -----2 bytes - required data-tag ----data | y bytes - optional 

The value of the tag determines whether the bytes following the tag are:

. attributes

- . data
- . the remainder of a single attribute where the tag specifies the type of the value.

# 3.2 Syntax of Encoding

The syntax below is ABNF [abnf] except `strings of literals' SHALL be case sensitive. For example `a' means lower case `a' and not upper case

Herriot, Butler, October 23, 1997, [Page 6]

```
Moore and Turner
                       Expires April 23, 1998
INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997
      In addition, SIGNED-BYTE and SIGNED-SHORT fields are represented
`Α'.
as `%x' values which show their range of values.
  ipp-message = ipp-request / ipp-response
  ipp-request = version operation
          *(xxx-attributes-tag xxx-attribute-sequence) data-tag data
  ipp-response = version status-code
          *(xxx-attributes-tag xxx-attribute-sequence) data-tag data
  xxx-attribute-sequence = *compound-attribute
       ; where "xxx" in the three rules above stands for any of the
  following
       ; values: "operation", "job", "printer" or "unsupported-job".
  version = major-version minor-version
  major-version = SIGNED-BYTE ; initially %d1
  minor-version = SIGNED-BYTE ; initially %d0
  operation = SIGNED-SHORT ; mapping from model defined below
  status-code = SIGNED-SHORT ; mapping from model defined below
  compound-attribute = attribute *additional-values
  attribute = value-tag name-length name value-length value
  additional-values = value-tag zero-name-length value-length value
  name-length = SIGNED-SHORT ; number of octets of `name'
  name = LALPHA *( LALPHA / DIGIT / "-" / "_" / "." )
  value-length = SIGNED-SHORT ; number of octets of `value'
  value = OCTET-STRING
  data = OCTET-STRING
  zero-name-length = %x00.00 ; name-length of 0
  operation-attributes-tag= %x01
                                          ; tag of 1
  job-attributes-tag = %x02
                                          ; tag of 2
                                          ; tag of 4
  printer-attributes-tag = %x04
  unsupported-job-attributes-tag = %x05
                                          ; tag of 5
  data-tag = \% x 03
                                                             ; tag of
  3
  value-tag = %x10-FF
 SIGNED-BYTE = BYTE
  SIGNED-SHORT = 2BYTE
  DIGIT = %x30-39 ; "0" to "9"
  LALPHA = %x61-7A ; "a" to "z"
```

BYTE = %x00-FF OCTET-STRING = \*BYTE

The syntax allows an xxx-attributestag to be present when the xxxattribute-sequence that follows is empty. The syntax is defined this way to allow for the response of Get-Jobs where no attributes are returned for some job-objects. Although it is RECOMMENDED that the sender not send an xxx-attributestag if there are no attributes (except in the Get-

Herriot, Butler,

October 23, 1997,

[Page 7]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

Jobs response just mentioned), the receiver MUST be able to decode such syntax.

#### 3.3 Version

The version SHALL consist of a major and minor version, each of which SHALL be represented by a SIGNED-BYTE. The protocol described in this document SHALL have a major version of 1 (0x01) and a minor version of **0** (0x00). The ABNF for these two bytes SHALL be %x01.00.

#### **<u>3.4</u>** Mapping of Operations

Operations are defined as enums in the model document. An operations enum value SHALL be encoded as a SIGNED-SHORT

Note: the values 0x4000 to 0xFFFF are reserved for private extensions.

#### **<u>3.5</u>** Mapping of Status-code

Status-codes are defined as enums in the model document. A status-code enum value SHALL be encoded as a SIGNED-SHORT

If an IPP status-code is returned, then the HTTP Status-Code MUST be 200 (OK). With any other HTTP Status-Code value, the HTTP response SHALL NOT contain an IPP message-body, and thus no IPP status-code is returned.

## <u>3.6</u> Tags

There are two kinds of tags:

- . delimiter tags: delimit major sections of the protocol, namely attributes and data
- . value tags: specify the type of each attribute value

#### <u>3.6.1</u> Delimiter Tags

The following table specifies the values for the delimiter tags:

Tag Value (Hex) Delimiter

0x00 reserved

0x01	operation-attributes-tag
0x02	job-attributes-tag
0x03	data-tag
0x04	printer-attributes-tag
0x05	unsupported-job-attributes-tag
0x06-0x0F	reserved for future delimiters

Herriot, Butler, October 23, 1997, [Page 8]

Moore and Turner

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

When an xxx-attributes-tag occurs in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are xxx attributes as defined in the model document, where xxx is operation, job, printer, unsupported-job.

Doing substitution for xxx in the above paragraph, this means the following. When an operation-attributes-tag occurs in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are operation attributes as defined in the model document. When an job-attributes-tag occurs in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are job attributes as defined in the model document. When an printerattributes as defined in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are printer attributes as defined in the model document. When an unsupported-jobattributes tag occurs in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are printer attributes as defined in the model document. When an unsupported-jobattributes-tag occurs in the protocol, it SHALL mean that the zero or more following attributes up to the next delimiter tag are unsupported-jobattributes as defined in the model document. When an that the zero or more following attributes up to the next delimiter tag are unsupported-jobattributes as defined in the model document.

Each of the four xxx-attributes-tags defined above is OPTIONAL in an operation and each SHALL occur at most once in an operation, except for job-attributes-tag in a Get-Jobs response which may occur zero or more times. The data-tag SHALL occur exactly once in an operation.

If an operation contains an operations-attribute-tag, it SHALL be the first tag delimiter. The data-tag SHALL be the last tag delimiter.

The order and presence of delimiter tags for each operation request and each operation response SHALL be that defined in the model document. For further details, see <u>Section 3.8</u> Mapping of Attribute Names and Appendix B: Mapping of Each Operation in the Encoding.

## 3.6.2 Value Tags

The remaining tables show values for the value-tag, which is the first octet of an attribute. The value-tag specifies the type of the value of the attribute. The value of the value-tag of an attribute SHALL either be a type value specified in the model document or an "out-of-band" value, such as "unsupported" or "default". If the value of value-tag for an attribute is not "out-of-band" and differs from the value type specified by the model document, then a printer receiving such a request MAY reject the attribute or just the value. A client receiving such a response MAY ignore the attribute or just the value.

If ipp-attribute-fidelity is true and a printer rejects a value, it is the same as rejecting the attribute. If ipp-attribute-fidelity is false and a printer rejects a value, or it a client rejects a value, then it is as if the attribute didn't have that value. If after rejecting values, the attribute no longer has any values the attribute is rejected.

Herriot, Butler, October 23, 1997, [Page 9]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

Note: the intent of the above rule is for servers to be able to understand text and name values when they don't support the naturalLanguage override for the value.

The following table specifies the "out-of-band" values for the valuetag.

Tag Value (Hex) Meaning

0x10	unsupported
0x11	default
0x12	no-value
0x13	compoundValue
0x14-0x1F	reserved for future "out-of-band" values.

The "unsupported" value SHALL be used in the attribute-sequence of an error response for those attributes which the printer does not support. The "default" value is reserved for future use of setting value back to their default value. The "no-value" value is used for the "no-value" value in model, e.g. when a document-attribute is returned as a set of values and an attribute has no specified value for one or more of the documents. The "compoundValue" SHALL be used to form a single value from a collection of values, and its value is the number of members forming the compound value, excluding the compoundValue. For example, a text value with a naturalLanguage override consists of 3 "values": a compoundValue with value 2, a naturalLanguage value and a text value.

The following table specifies the integer values for the value-tag

Tag Value (Hex)Meaning0x20reserved0x21integer0x22boolean0x23enum0x24-0x2Freserved for future integer types

NOTE: 0x20 is reserved for "generic integer" if should ever be needed. The following table specifies the octetString values for the value-tag

Tag Value (Hex) Meaning

0x30	octetString with an unspecified format
0x31	dateTime
0x32	resolution
0x33	rangeOfInteger
0x34	reserved for dictionary (in the future)
0x35-0x3F	reserved for future octetString types

Herriot, Butler, October 23, 1997, [Page 10]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

The following table specifies the character-string values for the valuetag

Tag Value (Hex)	Meaning
0.40	
0x40	reserved
0x41	text
0x42	name
0x43	reserved
0x44	keyword
0x45	uri
0x46	uriScheme
0x47	charSet
0x48	naturalLanguage
0x49	mediaType
0x4A-0x5F	reserved for future character string types

NOTE: 0x40 is reserved for "generic character-string" if should ever be needed.

The values 0x60-0xFF are reserved for future types. There are no values allocated for private extensions. A new type must be registered via the type 2 process.

## 3.7 Name-Lengths

The name-length field SHALL consist of a SIGNED-SHORT. This field SHALL specify the number of octets in the name field which follows the name-length field, excluding the two bytes of the name-length field.

If a name-length field has a value of zero, the following name field SHALL be empty, and the following value SHALL be treated as an additional value for the preceding attribute. Within an attributesequence, if two attributes have the same name, the first occurrence SHALL be ignored. The zero-length name is the only mechanism for multivalued attributes.

## 3.8 Mapping of Attribute Names

Some attributes are encoded in a special position. These attribute are:

. "printer-uri": The target printer-uri of each operation in the IPP model document SHALL be specified outside of the operation layer

as the request-URI on the Request-Line at the HTTP level.

- . "job-uri": The target job-uri of each operation in the IPP model document SHALL be specified outside of the operation layer as the request-URI on the Request-Line at the HTTP level.
- . "document-content": The attribute named "document-content" in the IPP model document SHALL become the "data" in the operation layer.

Herriot, Butler, October 23, 1997, [Page 11]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

. "status-code": The attribute named "status-code" in the IPP model document SHALL become the "status-code" field in the operation layer response.

The model document arranges the remaining attributes into groups for each operation request and response. Each such group SHALL be represented in the protocol by an xxx-attribute-sequence preceded by the appropriate xxx-attributes-tag (See the table below and <u>Appendix B</u>: Mapping of Each Operation in the Encoding). In addition, the order of these xxx-attributes-tags and xxx-attribute-sequences in the protocol SHALL be the same as in the model document, but the order of attributes within each xxx-attribute-sequence SHALL be unspecified. The table below maps the model document group name to xxx-attributes-sequence

Model Document Group xxx-attributes-sequence Operation Attributes operations-attributes-sequence Job Template Attributes job-attributes-sequence Job Object Attributes job-attributes-sequence Unsupported Attributes unsupported-job-attributes-sequence job-attributes-sequence Requested Attributes (Get-Attributes of job object) Requested Attributes (Getprinter-attributes-sequence Attributes of printer object) Document Content in a special position as described above ISSUE: coordinate this with the model document.

If an operation contains attributes from more than one job object (e.g. Get-Jobs response), the attributes from each job object SHALL be in a separate job-attribute-sequence, such that the attributes from the ith job object are in the ith job-attribute-sequence. See <u>Section 10</u> "Appendix B: Mapping of Each Operation in the Encoding" for table showing the application of the rules above.

#### 3.9 Value Lengths

Each attribute value SHALL be preceded by a SIGNED-SHORT which SHALL specify the number of octets in the value which follows this length, exclusive of the two bytes specifying the length.

For any of the types represented by binary signed integers, the sender MUST encode the value in exactly four octets..

For any of the types represented by character-strings, the sender MUST

encode the value with all the characters of the string and without any padding characters.

If a value-tag contains an "out-of-band" value, such as "unsupported", the value-length SHALL be 0 and the value empty " the value has no meaning when the value-tag has an "out-of-band" value. If a printer or client receives an operation with a nonzero value-length in this case, it SHALL ignore the value field.

Herriot, Butler, October 23, 1997, [Page 12]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

#### **<u>3.10</u>** Mapping of Attribute Values

The following SHALL be the mapping of attribute values to their IPP encoding in the value field. The syntax types are defined in the IPP model document.

Encoding Syntax of Attribute Value text an octet string whose charset and language is that specified within the operation request or response. The attributes-charset attribute with a value of type `charset' MUST be in the operationsattribute sequence unless the request or response contains no attributes. It specifies the charset for all text and name values of attributes. The attributes-natural-language attribute with a value of type `naturalLanguage' MUST be in the operations-attribute sequence unless the request or response contains no attributes. It specifies the language for all text and name values of attributes unless overridden. The language can be overridden on a per-object or a per-value basis. The language can be overridden on a per-object basis only for a job-sequence within a Get-Jobs response. If the attributes-natural-language attribute is present within such a context, it must have a value of type `naturalLanguage' and it overrides the language for all text and name attributes within the job-attributes sequence containing it, but not for attributes in any other xxx-attribute-sequence. The language can be overridden on a per-value basis by syntactically preceding the text or name value by two values: a value of type compoundValue whose value is 2 and a value of type naturalLanguage whose value is the language override. From a protocol syntax view, the compoundValue, the naturalLanguage value and the text or name value appear as three separate values of a single attribute, but from a semantic view, the Printer treats them as a single value

where the naturalLanguage value overrides the language of the immediately following text or name value in the attribute. Any text or name values in the same or other attributes are not affected by the override. If an attribute consists of a single text or name value, the language value turns it into an attribute with two values from a syntactic view. The text is encoded in "network byte order" with

Herriot, Butler,

October 23, 1997,

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

Syntax of Encoding Attribute Value

		<pre>second SIGNED-INTEGER contains the value of prtMarkerAddressabilityFeedDir. The SIGNED-BYTE contains the value of prtMarkerAddressabilityUnit. Note: the latter value is either 3 (tenThousandsOfInches) or 4 (micrometers) and the addressability is in 10,000</pre>
		units of measure. Thus the SIGNED-INTEGERS
		represent integral values in either dots-per-inch
		or dots-per-centimeter.
range0f	integer	Eight octets consisting of 2 SIGNED-INTEGERs. The
		first SIGNED-INTEGERs contains the lowest value
		of the range and the second SIGNED-INTEGERs
		contains the highest value of the range
1set0f	Х	encoding according to the rules for an attribute with more than more value. Each value X is
		encoded according to the rules for encoding its
		type.

The type of the value in the model document determines the encoding in the value and the value of the value-tag.

#### <u>3.11</u> Data

The data part SHALL include any data required by the operation

#### **<u>4</u>**. Encoding of Transport Layer

HTTP/1.1 shall be the transport layer for this protocol.

The operation layer has been designed with the assumption that the transport layer contains the following information:

- . the URI of the target job or printer operation
- . the total length of the data in the operation layer, either as a single length or as a sequence of chunks each with a length.

It is REQUIRED that a printer support HTTP over port 80, though a printer may support HTTP over port 516 or some other port. In addition, a printer may have to support another port for secure connections.

Note: Consistent with <u>RFC 2068</u> (HTTP/1.1), HTTP URI's for IPP implicitly

reference port 80. If a URI references some other port, the port number must be explicitly specified in the URI.

Each HTTP operation shall use the POST method where the request-URI is the object target of the operation, and where the "Content-Type" of the message-body in each request and response shall be "application/ipp". The message-body shall contain the operation layer and shall have the syntax described in <u>section 3.2</u> "Syntax of Encoding". A client

Herriot, Butler, October 23, 1997, [Page 15]

Moore and Turner

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

implementation SHALL adhere to the rules for a client described in RFC 2068 [r2068]. A printer (server) implementation SHALL adhere the rules for an origin server described in RFC 2068. In the following sections, there are a tables of all HTTP headers which describe their use in an IPP client or server. The following is an explanation of each column in these tables.

- . the "header" column contains the name of a header
- . the "request/client" column indicates whether a client sends the header.
- . the "request/ server" column indicates whether a server supports the header when received.
- . the "response/ server" column indicates whether a server sends the header.
- . the "response /client" column indicates whether a client supports the header when received.
- . the "values and conditions" column specifies the allowed header values and the conditions for the header to be present in a request/response.

The table for "request headers" does not have columns for responses, and the table for "response headers" does not have columns for requests.

The following is an explanation of the values in the "request/client" and "response/ server" columns.

- . must: the client or server MUST send the header,
- . must-if: the client or server MUST send the header when the condition described in the "values and conditions" column is met,
- . may: the client or server MAY send the header
- . not: the client or server SHOULD NOT send the header. It is not relevant to an IPP implementation.

The following is an explanation of the values in the "response/client" and "request/ server" columns.

- . must: the client or server MUST support the header,
- . may: the client or server MAY support the header
- . not: the client or server SHOULD NOT support the header. It is not relevant to an IPP implementation.

## **4.1** General Headers

The following is a table for the general headers.

 $\ensuremath{\mathsf{ISSUE}}$  : an  $\ensuremath{\mathsf{HTTP}}$  expert should review these tables for accuracy.

General- Request Response Values and Conditions Header

Client Server Server Client

### **<u>5</u>**. Security Considerations

When utilizing HTTP 1.1 as a transport of IPP, the security considerations outlined in <u>RFC 2068</u> [r2068] apply. Specifically, IPP servers can generate a 401 "Unauthorized" response code to request client authentication and IPP clients should correctly respond with the proper "Authorization" header. Both Basic Authentication (<u>RFC 2068</u>) and Digest Authentication (<u>RFC 2069</u>) [r2069] flavors of authentication SHALL be supported. The server chooses which type(s) of authentication to accept. Digest Authentication is a more secure method, and is always preferred to Basic Authentication.

For secure communication (privacy in particular), IPP SHOULD be run using a secure communications channel. For this purpose it is the intention to define standardization of IPP in combination with Transport Layer Security (TLS), currently under development in the IETF, when the TLS specifications are agreed and on the IETF standards track.

As an intercept solution for secure communication, the Secure Socket

Layer 3.0 (SSL3) could be used, but be warned that such implementations may not be able to interoperate with a future standardized IPP and TLS solution. Appendix C gives some hints to implementors wanting to use SSL3 as intercept solution.

It is possible to combine the techniques, HTTP 1.1 client authentication (either basic or digest) with a secure communications channel. Together

Herriot, Butler, October 23, 1997, [Page 19]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

the two are more secure than client authentication and they perform user authentication.

See further discussion of IPP security concepts in the model document [<u>ipp-m</u>].

## 10. Appendix B: Mapping of Each Operation in the Encoding

The next three tables show the results of applying the rules above to the operations defined in the IPP model document. There is no information in these tables that cannot be derived from the rules presented in <u>Section 3.8</u> "Mapping of Attribute Names".

The following table shows the mapping of all IPP model-document request attributes to an appropriate xxx-attribute-sequence or special position in the protocol.

The table below shows the attributes for operations sent to a Printer URI.

Operation	operation attributes	job attributes	special position
Print-Job	attributes- charset attributes- natural- language job-name document-name ipp-attribute- fidelity document-	job-template attributes	document-content

	charset	
	document-	
	natural-	
	language	
Create-Job or	attributes-	job-template
Validate-Job	charset	attributes
	attributes-	
	natural-

Moore and Turner Expires April 23, 1998							
INTERNET-DRAFT	IPP/1.0:	Protocol Spe	cification	October 23, 19	97		
Note: the job-attributes are present only if the server returns the status code of successful-ok or successful-ok-ignored-or-substituted-attributes.							
Operation	operation attributes	job- attributes	printer- attributes	special position			
Cancel-Job	attributes- charset attributes- natural- language						
status- code					status-		
	message						
Get-Attributes (of a job)	attributes- charset attributes- natural- language status- message	requested attributes		status-code			
Get-Attributes (of a printer)			requested attributes	status-code			
Get-Jobs	attributes- charset attributes- natural- language status- message	requested attributes (see the Note below)		status-code			

Note for Get-Jobs: there is a separate job-attribute-sequence containing requested-attributes for each job object in the response

# **<u>11</u>**. <u>Appendix C</u>: Hints to implementors using IPP with SSL3

WARNING: Clients and IPP objects using intermediate secure connection protocol solutions such as IPP in combination with Secure Socket Layer Version 3 (SSL3), which are developed in advance of IPP and TLS standardization, might not be interoperable with IPP and TLS standardsconforming clients and IPP objects.

Herriot, Butler, October 23, 1997, [Page 32]

Moore and Turner Expires April 23, 1998

INTERNET-DRAFT IPP/1.0: Protocol Specification October 23, 1997

An assumption is that the URI for a secure IPP Printer object has been found by means outside the IPP printing protocol, via a directory service, web site or other means.

IPP provides a transparent connection to SSL by calling the corresponding URL (a https URI connects by default to port 443). However, the following functions can be provided to ease the integration of IPP with SSL during implementation.

connect (URI), returns a status.

"connect" makes an https call and returns the immediate status of the connection as returned by SSL to the user. The status values are explained in <u>section 5.4.2</u> of the SSL document [<u>ssl</u>].

A session-id may also be retained to later resume a session. The SSL handshake protocol may also require the cipher specifications supported by the client, key length of the ciphers, compression methods, certificates, etc. These should be sent to the server and hence should be available to the IPP client (although as part of administration features).

disconnect (session)

to disconnect a particular session.

The session-id available from the "connect" could be used.

resume (session)

to reconnect using a previous session-id.

The availability of this information as administration features are left for implementors, and need not be standardized at this time
