Definitions of Managed Objects for iSCSI

Status of this Memo

By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she becomes aware will be disclosed, in accordance with [Section 6 of BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/ietf/1id-abstracts.html>.

The list of Internet-Draft Shadow Directories can be accessed at
<http://www.ietf.org/shadow.html>.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP based internets. In particular it defines objects for managing a client using the iSCSI (SCSI over TCP) protocol.

[1. Introduction](#)

This document defines a MIB module for iSCSI [[RFC3720](#)], used to manage devices which implement the iSCSI protocol.

Bakke, Muchow

Expires April 2006

[Page 2]

2. Specification of Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

3. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to [section 7 of RFC 3410](#) [[RFC3410](#)].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, [RFC 2578](#) [[RFC2578](#)], STD 58, [RFC 2579](#) [[RFC2579](#)] and STD 58, [RFC 2580](#) [[RFC2580](#)].

4. Relationship to Other MIB modules

The iSCSI MIB module is normally layered between the SCSI MIB module [[SCSIMIB](#)] (work in progress) and the TCP MIB module [[RFC2012](#)], and makes use of the IPS Identity Authentication MIB module [[AUTHMIB](#)] (work in progress). Here is how these modules are related:

SCSI MIB Within systems where a SCSI layer is present, each `iscsiNode`, whether it has an initiator role, target role, or both, is related to one SCSI device within the SCSI MIB module. In this case, the `iscsiNodeTransportType` attribute points to the SCSI transport object within the SCSI MIB module, which in turn contains an attribute that points back to the `iscsiNode`. In this way, a management station can navigate between the two MIB modules. In systems where a SCSI layer is not present, such as within an iSCSI proxy device, the `iscsiNodeTransportType` attribute points to the appropriate corresponding object within the appropriate MIB, or is left blank.

TCP MIB Each iSCSI connection is related to one transport-level connection. Currently, iSCSI uses only TCP; the iSCSI connection is related to a TCP connection using its normal (protocol, source address, source port, destination address, destination port) 5-tuple.

Bakke, Muchow

Expires April 2006

[Page 3]

AUTH MIB Each iSCSI node that serves a target role can have a list of authorized initiators. Each of the entries in this list points to an identity within the IPS Identity Authentication MIB module that will be allowed to access the target. iSCSI nodes that serve in an initiator role can also have a list of authorized targets. Each of the entries in this list points to an identity within the Auth MIB module to which the initiator should attempt to establish sessions. The Auth MIB module includes information used to identify initiators and targets by their iSCSI name, IP address, and/or credentials.

This MIB module imports objects from RFCs 2578 [[RFC2578](#)], 2579 [[RFC2579](#)], 2580 [[RFC2580](#)], and 3411 [[RFC3411](#)]. It also imports textual conventions from the INET-ADDRESS-MIB [[RFC4001](#)].

5. Relationship to SNMP Contexts

Each non-scalar object in the iSCSI MIB module is indexed first by an iSCSI Instance. Each instance is a collection of nodes, portals, sessions, etc., that can define a physical or virtual partitioning of an iSCSI-capable device. The use of an instance works well with partitionable or hierarchical storage devices and fits in logically with other management schemes. Instances do not replace SNMP contexts, however they do provide a very simple way to assign a virtual or physical portion of a device to one or more SNMP contexts, without having to do so for each individual node, portal, and session row.

6. Discussion

This MIB module structure supplies configuration, fault, and statistics information for iSCSI devices [[RFC3720](#)]. It is structured around the well-known iSCSI objects, such as targets, initiators, sessions, connections, and the like.

This MIB module may also be used to configure access to iSCSI targets, by creating iSCSI Portals and authorization list entries.

It is worthwhile to note that this is an iSCSI MIB module and as such reflects only iSCSI objects. This module does not contain information about the SCSI-layer attributes of a device. If a SCSI layer is present, the SCSI MIB module, currently under development, may be used to manage SCSI information for a device.

Bakke, Muchow

Expires April 2006

[Page 4]

The iSCSI MIB module consists of several "objects", each of which is represented by one or more tables. This section contains a brief description of the "object" hierarchy and a description of each object, followed by a discussion of the actual table structure within the objects.

6.1. iSCSI MIB Object Model

The top-level object in this structure is the iSCSI instance, which "contains" all of the other objects.

```
iscsiInstance
  -- A distinct iSCSI entity within the managed system.
  iscsiPortal
    -- An IP address used by this instance
    iscsiTargetPortal
      -- Contains portal information relevant when the portal
      -- is used to listen for connections to its targets.
    iscsiInitiatorPortal
      -- Contains portal information relevant when the portal
      -- is used to initiate connections to other targets.
  iscsiNode
    -- An iSCSI node can act as an initiator, a target, or both.
    -- Contains generic (non-role-specific) information.
  iscsiTarget
    -- Target-specific iSCSI node information.
    iscsiTgtAuth
      -- A list of initiator identities that are allowed
      -- access to this target.
  iscsiInitiator
    -- Initiator-specific iSCSI node information.
    iscsiIntrAuth
      -- A list of target identities to which this initiator
      -- is configured to establish sessions.
  iscsiSession
    -- An active iSCSI session between an initiator and target.
    -- The session's direction may be Inbound (outside
    -- initiator to our target) or Outbound (our initiator to
    -- an outside target).
  iscsiConnection
    -- An active TCP connection within an iSCSI session
```

An iSCSI Node can be an initiator, a target, or both. The iSCSI Node's portals may be used to initiate connections (initiator) or listen for connections (target), depending on whether the iSCSI Node is acting as an initiator or target. The iSCSI MIB module assumes that any target may be accessed via any portal that can take on a target role, although other access controls not reflected in the

Bakke, Muchow

Expires April 2006

[Page 5]

module might limit this.

6.2. iSCSI MIB Table Structure

Each iSCSI object exports one or more tables: an attributes table, and zero or more statistics tables which augment the attributes table. Since iSCSI is an evolving standard, it is much cleaner to provide statistics and attributes as separate tables, allowing attributes and statistics to be added independently. In a few cases, there are multiple categories of statistics that will likely grow; in this case, an object will contain multiple statistics tables.

```
iscsiObjects
  iscsiDescriptors
  iscsiInstance
    iscsiInstanceAttributesTable
    iscsiInstanceSsnErrorStatsTable
      -- Counts abnormal session terminations
  iscsiPortal
    iscsiPortalAttributesTable
  iscsiTargetPortal
    iscsiTgtPortalAttributesTable
  iscsiInitiatorPortal
    iscsiIntrPortalAttributesTable
  iscsiNode
    iscsiNodeAttributesTable
  iscsiTarget
    iscsiTargetAttributesTable
    iscsiTargetLoginStatsTable
      -- Counts successful and unsuccessful logins
    iscsiTargetLogoutStatsTable
      -- Counts normal and abnormal logouts
  iscsiTgtAuthorization
    iscsiTgtAuthAttributesTable
  iscsiInitiator
    iscsiInitiatorAttributesTable
    iscsiInitiatorLoginStatsTable
      -- Counts successful and unsuccessful logins
    iscsiInitiatorLogoutStatsTable
      -- Counts normal and abnormal logouts
  iscsiIntrAuthorization
    iscsiIntrAuthAttributesTable
  iscsiSession
    iscsiSessionAttributesTable
    iscsiSessionStatsTable
      -- Performance-related counts (requests, responses, bytes)
    iscsiSessionCxnErrorStatsTable
      -- Counts digest errors, connection errors, etc.
```

Bakke, Muchow

Expires April 2006

[Page 6]

```
iscsiConnection
  iscsiConnectionAttributesTable
```

Note that this module does not attempt to count everything that could be counted; it is designed to include only those counters that would be useful for identifying performance, security, and fault problems from a management station.

6.3. iscsiInstance

The iscsiInstanceAttributesTable is the primary table of the iSCSI MIB module. Every table entry in this module is "owned" by exactly one iSCSI instance; all other table entries in the module include this table's index as their primary index.

Most implementations will include just one iSCSI instance row in this table. However, this table exists to allow for multiple virtual instances. For example, many IP routing products now allow multiple virtual routers. The iSCSI MIB module has the same premise; a large system could be "partitioned" into multiple, distinct virtual systems.

This also allows a single SNMP agent to proxy for multiple subsystems, perhaps a set of stackable devices, each of which have one or even more instances.

The instance attributes include the iSCSI vendor and version, as well as information on the last target or initiator at the other end of a session that caused a session failure.

The iscsiInstanceSsnErrorStatsTable augments the attributes table, and provides statistics on session failures due to digest, connection, or iSCSI format errors.

6.4. iscsiPortal

The iscsiPortalAttributesTable lists iSCSI portals that can either be used to listen for connections to targets, or initiate connections to other targets, or both.

Each row in the table includes an IP address (either v4 or v6), and a transport protocol (currently only TCP is defined). Each portal may have additional attributes, depending on whether it is an initiator portal, a target portal, or both. Initiator portals also have portal tags; these are placed in corresponding rows in the iscsiIntrPortalAttributesTable. Target portals have both portal tags and ports (e.g. TCP listen ports if the transport protocol is TCP);

Bakke, Muchow

Expires April 2006

[Page 7]

these are placed in rows in the `iscsiTgtPortalAttributesTable`.

Portal rows, along with their initiator and target portal counterparts, may be created and destroyed through this MIB module by a management station. Rows in the initiator and target portal tables are created and destroyed automatically by the agent, whenever a row is created or destroyed in the `iscsiPortalAttributesTable`, or if the value of `iscsiPortalRoles` changes. Attributes in these tables may then be modified by the management station if the agent implementation allows.

When created by a management station, the `iscsiPortalRoles` attribute is used to control row creation in the initiator and target portal tables. Creating a row with the `targetTypePortal` bit set in `iscsiPortalRoles` will cause the implementation to start listening for iSCSI connections on the portal. Creating a row with the `initiatorTypePortal` bit set in `iscsiPortalRoles` will not necessarily cause connections to be established; it is left to the implementation whether and when to make use of the portal. Both bits may be set if the portal is to be used by both initiator and target nodes.

When deleting a row in the `iscsiPortalAttributesTable`, all connections associated with that row are terminated. The implementation may either terminate the connection immediately, or request a clean shutdown as specified in [[RFC3720](#)]. An outbound connection (when an `iscsiInitiatorPortal` is deleted) matches the portal if its `iscsiCxnLocalAddr` matches the `iscsiPortalAddr`. An inbound connection (when an `iscsiTargetPortal` is deleted) matches the portal if both its `iscsiCxnLocalAddr` matches the `iscsiPortalAddr`, and the `iscsiCxnLocalPort` matches the `iscsiTargetPortalPort`.

Individual objects within a row in this table may not be modified while the row is active. For instance, changing the IP address of a portal requires that the rows associated with the old IP address be deleted, and new rows be created (in either order).

6.5. `iscsiTargetPortal`

The `iscsiTgtPortalAttributesTable` contains target-specific attributes for iSCSI Portals. Rows in this table use the same indices as their corresponding rows in the `iscsiPortalAttributesTable`, with the addition of `iscsiNodeIndex`.

Rows in this table are created when the `targetTypePortal` bit is set in the `iscsiPortalRoles` attribute of the corresponding `iscsiPortalAttributesEntry`; they are destroyed when this bit is cleared.

Bakke, Muchow

Expires April 2006

[Page 8]

This table contains the TCP (or other protocol) port on which the socket is listening for incoming connections. It also includes a portal group aggregation tag; iSCSI target portals within this instance sharing the same tag can contain connections within the same session.

This table will be empty for iSCSI instances that contain only initiators (such as iSCSI host driver implementations).

Many implementations use the same target portal tag and protocol port for all nodes accessed via a portal. These implementations will create a single row in the `iscsiTgtPortalAttributeTable`, with an `iscsiNodeIndex` of zero.

Other implementations do not use the same tag and/or port for all nodes; these implementations will create a row in this table for each (portal, node) tuple, using `iscsiNodeIndex` to designate the node for this portal tag and port.

6.6. `iscsiInitiatorPortal`

The `iscsiIntrPortalAttributesTable` contains initiator-specific objects for iSCSI Portals. Rows in this table use the same indices as their corresponding entries in the `iscsiPortalAttributesTable`. A row in this table is created when the `initiatorTypePortal` bit is set in the `iscsiPortalRoles` attribute; it is destroyed when this bit is cleared.

Each row in this table contains a portal group aggregation tag, indicating which portals an initiator may use together within a multiple-connection session.

This table will be empty for iSCSI instances that contain only targets (such as most iSCSI devices).

Many implementations use the same initiator tag for all nodes accessing targets via a given portal. These implementations will create a single row in `iscsiIntrPortalAttributeTable`, with an `iscsiNodeIndex` of zero.

Other implementations do not use the same tag and/or port for all nodes; these implementations will create a row in this table for each (portal, node) tuple, using `iscsiNodeIndex` to designate the node for this portal tag and port.

Bakke, Muchow

Expires April 2006

[Page 9]

6.7. iscsiNode

The iscsiNodeAttributesTable contains a list of iSCSI nodes, each of which may have an initiator role, a target role, or both.

This table contains the node's attributes which are common to both roles, such as its iSCSI Name and alias string. Attributes specific to initiators or targets are available in the iscsiTarget and iscsiInitiator objects. Each row in this table that can fulfill a target role has a corresponding row in the iscsiTarget table; each entry that fulfills an initiator role has a row in the iscsiInitiator table. Nodes such as copy managers that can take on both roles have a corresponding row in each table.

This table also contains the login negotiations preferences for this node. These objects indicate the values this node will offer or prefer in the operational negotiation phase of the login process.

For most implementations, each entry in the table also contains a RowPointer to the transport table entry in the SCSI MIB module which this iSCSI node represents. For implementations without a standard SCSI layer above iSCSI, such as an iSCSI proxy or gateway, this RowPointer can point to a row in an implementation specific table that this iSCSI node represents.

6.8. iscsiTarget

The iscsiTargetAttributesTable contains target-specific attributes for iSCSI nodes. Each entry in this table uses the same index values as its corresponding iscsiNode entry.

This table contains attributes used to indicate the last failure that was (or should have been) sent as a notification.

This table is augmented by the iscsiTargetLoginStatsTable and the iscsiTargetLogoutStatsTable, which count the numbers of normal and abnormal logins and logouts to this target.

6.9. iscsiTgtAuthorization

The iscsiTgtAuthAttributesTable contains an entry for each initiator identifier that will be allowed to access the target under which it appears. Each entry contains a RowPointer to a user identity in the IPS Authorization MIB module, which contains the name, address, and credential information necessary to authenticate the initiator.

Bakke, Muchow

Expires April 2006

[Page 10]

6.10. iscsiInitiator

The iscsiInitiatorAttributesTable contains a list of initiator-specific attributes for iSCSI nodes. Each entry in this table uses the same index values as its corresponding iscsiNode entry.

Most implementations will include a single entry in this table, regardless of the number of physical interfaces the initiator may use.

This table is augmented by the iscsiInitiatorLoginStatsTable and the iscsiInitiatorLogoutStatsTable, which count the numbers of normal and abnormal logins and logouts from this initiator.

6.11. iscsiIntrAuthorization

The iscsiIntrAuthAttributesTable contains an entry for each target identifier to which the initiator is configured to establish a session.

Each entry contains a RowPointer to a user identity in the IPS Authorization MIB module, which contains the name, address, and credential information necessary to identify (for discovery purposes) and authenticate the target.

6.12. iscsiSession

The iscsiSessionAttributesTable contains a set of rows that list the sessions known to be existing locally for each node in each iSCSI instance.

The session type for each session indicates whether the session is used for normal SCSI commands or for discovery using the SendTargets text command. Discovery sessions that do not belong to any particular node have a node index attribute of zero.

The session direction for each session indicates whether it is an Inbound Session or an Outbound Session. Inbound sessions are from some other initiator to the target node under which the session appears. Outbound sessions are from the initiator node under which the session appears to a target outside this iSCSI instance.

Many attributes may be negotiated when starting an iSCSI session. Most of these attributes are included in the session object.

Some attributes, such as the integrity and authentication schemes, have some standard values which can be extended by vendors to include their own schemes. These contain an object identifier, rather than

Bakke, Muchow

Expires April 2006

[Page 11]

the expected enumerated type, to allow these values to be extended by other MIB modules, such as an enterprise MIB module.

The `iscsiSessionStatsTable` includes statistics related to performance; it counts iSCSI data bytes and PDUs.

For implementations that support error recovery without terminating a session, the `iscsiSessionCxnErrorStatsTable` contains counters for the numbers of digest and connection errors that have occurred within the session.

6.13. `iscsiConnection`

The `iscsiConnectionAttributesTable` contains a list of active connections within each session. It contains the IP addresses and TCP (or other protocol) ports of both the local and remote side of the connection. These may be used to locate other connection-related information and statistics in the TCP MIB module [[RFC2012](#)].

The attributes table also contains a connection state. This state is not meant to directly map to the state tables included within the iSCSI specification; they are meant to be simplified, higher-level definitions of connection state that provide information more useful to a user or network manager.

No statistics are kept for connections.

6.14. IP Addresses and TCP Port Numbers

The IP addresses in this module are represented by two attributes, one of type `InetAddressType`, and the other of type `InetAddress`. These are taken from [[RFC4001](#)], which specifies how to support addresses that may be either IPv4 or IPv6.

The TCP port numbers that appear in a few of the structures are described as simply port numbers, with a protocol attribute indicating whether they are TCP ports, or something else. This will allow the module to be compatible with iSCSI over transports other than TCP in the future.

6.15. Descriptors: Using OIDs in Place of Enumerated Types

The iSCSI MIB module has a few attributes, namely the digest method attributes, where an enumerated type would work well, except that an implementation may need to extend the attribute and add types of its own. To make this work, this MIB module defines a set of object identities within the `iscsiDescriptors` subtree. Each of these object identities is basically an enumerated type.

Bakke, Muchow

Expires April 2006

[Page 12]

Attributes that make use of these object identities have a value which is an OID instead of an enumerated type. These OIDs can either indicate the object identities defined in this module, or object identities defined elsewhere, such as in an enterprise MIB module. Those implementations that add their own digest methods should also define a corresponding object identity for each of these methods within their own enterprise MIB module, and return its OID whenever one of these attributes is using that method.

6.16. Notifications

Three notifications are provided. One is sent by an initiator detecting a critical login failure; another is sent by a target detecting a critical login failure, and the third is sent upon a session being terminated due to an abnormal connection or digest failure. Critical failures are defined as those that may expose security-related problems that may require immediate action, such as failures due to authentication, authorization, or negotiation problems. Attributes in the initiator, target, and instance objects provide the information necessary to send in the notification, such as the initiator or target name and IP address at the other end that may have caused the failure.

To avoid sending an excessive number of notifications due to multiple errors counted, an SNMP agent implementing the iSCSI MIB module SHOULD NOT send more than three iSCSI notifications in any 10-second period.

The 3-in-10 rule was chosen because one notification every three seconds was deemed often enough, but should two or three different notifications happen at the same time, it would not be desirable to suppress them. Three notifications in ten seconds is a happy medium, where a short burst of notifications is allowed, without inundating the network and/or notification host with a large number of notifications.

DESCRIPTION

"A pointer to the corresponding row in the appropriate table for this SCSI transport, thereby allowing management stations to locate the SCSI-level device that is represented by this iscsiNode. For example, it will usually point to the corresponding scsiTrnspt object in the SCSI MIB module.

Bakke, Muchow

Expires April 2006

[Page 32]

If no corresponding row exists, the value 0.0 must be used to indicate this."

8. Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

`iscsiPortalAttributesTable`, `iscsiTgtPortalAttributesTable`, and `iscsiIntrPortalAttributes` table can be used to add or remove IP addresses to be used by iSCSI.

`iscsiTgtAuthAttributesTable` entries can be added or removed, to allow or disallow access to a target by an initiator.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

`iscsiNodeAttributesTable`, `iscsiTargetAttributesTable`, and `iscsiTgtAuthorization` can be used to glean information needed to make connections to the iSCSI targets this module represents. However, it is the responsibility of the initiators and targets involved to authenticate each other to ensure that an inappropriately advertised or discovered initiator or target does not compromise their security. These issues are discussed in [[RFC3720](#)].

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementors consider the security features as provided by the SNMPv3 framework (see [[RFC3410](#)], [section 8](#)), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator

Bakke, Muchow

[Page 79]

responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

9. IANA Considerations

9.1. OID Assignment

IANA is requested to make a MIB OID assignment under the mib-2 branch.

12. Acknowledgments

In addition to the authors, several people contributed to the development of this MIB module. Thanks especially to those who took the time to participate in our weekly conference calls to build our requirements, object models, table structures, and attributes: John Hufferd, Tom McSweeney (IBM), Kevin Gibbons (Nishan Systems), Chad Gregory (Intel), Jack Harwood (EMC), Hari Mudaliar (Adaptec), Ie Wei Njoo (Agilent), Lawrence Lamers (SAN Valley), Satish Mali (Stonefly Networks), and William Terrell (Troika).

Special thanks to Tom McSweeney, Ie Wei Njoo, and Kevin Gibbons, who wrote the descriptions for many of the tables and attributes in this MIB module, to Ayman Ghanem for finding and suggesting changes for many problems in this module, and to Keith McCloghrie for serving as advisor to the team.
