                    Link Scoped IPv6 Multicast Addresses
                  <draft-ietf-ipv6-link-scoped-mcast-05.txt>

Status of this Memo

    By submitting this Internet-Draft, I certify that any applicable
    patent or other IPR claims of which I am aware have been disclosed,
    and any of which I become aware will be disclosed, in accordance
    with [RFC 3668](RFC 3668).

    Internet-Drafts are working documents of the Internet Engineering
    Task Force (IETF), its areas, and its working groups. Note that
    other groups may also distribute working documents as Internet-
    Drafts.

    Internet-Drafts are draft documents valid for a maximum of six
    months and may be updated, replaced, or obsoleted by other docu-
    ments at any time. It is inappropriate to use Internet-Drafts as
    reference material or to cite them other than as "work in
    progress."

    The list of current Internet-Drafts can be accessed at
    http://www.ietf.org/ietf/1id-abstracts.txt.

    http://www.ietf.org/shadow.html.

    This Internet-Draft will expire on February 2005.

Abstract

    This document specifies an extension to the multicast addressing
    architecture of the IPv6 protocol. The extension allows for the use
    of interface-IDs to allocate multicast addresses. When a link-
    local unicast address is configured at each interface of a node, an
    interface ID is uniquely determined. By delegating multicast
    addresses at the same time as the interface ID, each node can
    generate their unique multicast addresses automatically without
    conflicts. Basically, it is preferred to use this method for the
    link-local scope rather than unicast-prefix-based IPv6 multicast

addresses [RFC 3306].

_____

Table of Contents:

1. Introduction

    This specification defines an extension to the multicast portion of
    the IPv6 addressing architecture [RFC 3513]. The current
    architecture does not contain any built-in support for dynamic
    address allocation. The extension allows for use of interface-IDs
    to allocate multicast addresses. When a link-local unicast address
    is configured at each interface of a node, an interface ID is
    uniquely determined. By delegating multicast addresses at the same
    time as the interface ID, each node can generate their unique
    multicast addresses automatically without conflicts.

    Basically, it is preferred to use this method for the link-local
    scope rather than unicast-prefix-based IPv6 multicast addresses
    [RFC 3306]. This document restricts the usage of defined fields
    such as scope, plen and network prefix fields of [RFC 3306].
    Therefore, this document specifies encoded information for link-
    local scope in the multicast addresses.

    The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
    "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in
    this document are to be interpreted as described in [RFC 2119].

2. Applicability

The allocation technique in this document is designed to be used in any environment in which link-local scope IPv6 multicast addresses are assigned or selected. Especially, this method goes well with nodes supplying multicast services in a zeroconf/serverless environment. For example, multicast addresses less than or equal to link-local scope are themselves generated by nodes supplying multicast services without conflicts.

Consequently, this technique MUST be used for link scoped multicast addresses. If you want to use multicast addresses greater than link-local scope, you need other methods such as [RFC 3306].

3. Link scoped multicast address format

[RFC 3306] defines the following format of unicast-prefix-based IPv6 multicast addresses:

```
| 8      | 4 | 4 | 8      | 8      |      64        | 32       |
+--------+----+----+-------+-------+---------------+----------+
|11111111|flgs|scop|reserved|  plen  | network prefix | group ID |
+--------+----+----+-------+-------+---------------+----------+
```
   Figure 1: Unicast-Prefix-based IPv6 multicast address format

This document specifies a new format that incorporates interface ID information in the multicast addresses. The idea of delegating multicast addresses at the same time as the interface ID can be applicable to link-local scope.

Figure 2 illustrates the new format for link scoped multicast addresses.

```
| 8      | 4 | 4 | 8      | 8      |      64        | 32       |
+--------+----+----+-------+-------+---------------+----------+
|11111111|flgs|scop|reserved|  LSM   |  Interface ID  | group ID |
+--------+----+----+-------+-------+---------------+----------+
```
     Figure 2: Link scoped multicast IPv6 address format

flgs MUST be "0011". (The first two bits have been yet undefined,
sent as zero and ignored on receipt.) flgs MUST use the same flag
defined in section 4 of [RFC 3306].

scop MUST be <= 2. It is preferred to use this method for the link-
local scope rather than unicast-prefix-based IPv6 multicast
addresses [RFC 3306].

The reserved field MUST be zero.

LSM (Link Scoped Multicast) field MUST be "1111 1111" which maps to
plen field in [RFC 3306], whereas the plen of [RFC 3306] MUST NOT
be greater than 64.

That is, flgs, scop, and LSM fields are used to identify whether an
address is a multicast address as specified in this document and to
be processed any further.

Interface ID field is used to distinguish each node from others.
And this value is obtained from the IEEE EUI-64 based interface
identifier of the link-local unicast IPv6 address. Given the use
of this method for link-local scope, the interface ID embedded in
the multicast address SHOULD come from the interface ID of the
link-local unicast address on the interface after DAD has
completed. That is, the creation of the multicast address MUST

occur after DAD has completed as part of the auto-config process.

Group ID is generated to indicate multicast application and is used
to guarantee its uniqueness only in the host. It may also be set
on the basis of the guidelines outlined in [RFC 3307].

The lifetime of link scoped multicast addresses has no dependency
on the Valid Lifetime field in the Prefix Information option,
corresponding to the unicast address being used, contained in the
Router Advertisement message [RFC 2461].

4. Example

This is an example of link scoped IPv6 multicast addresses. For
example in an ethernet environment, if the link-local unicast
address is FE80::A12:34FF:FE56:7890, the link scoped multicast
prefix of the node is FF32:00FF:A12:34FF:FE56:7890::/96.

5. Considerations

   The link scoped multicast address format supports source-specific
   multicast addresses by the same method, as defined by [RFC 3306].

6. Security Considerations

   [RFC 3041] describes the privacy extension to IPv6 stateless
   address autoconfiguration for an interface ID. The interface ID,
   generated by [RFC 3041], is also used in this method since the
   uniqueness is verified by DAD procedure as part of the secure auto-
   config process.

7. Acknowledgements

   We would like to thank Dave Thaler and Brian Haberman for their
   comments related to the consistency between the unicast prefix-
   based multicast addresses [RFC 3306] and this one. Special thanks
   are due to Erik Nordmark and Pekka Savola for valuable comments.
