IS-IS Routing with Reverse Metric
draft-ietf-isis-reverse-metric-08

Abstract

This document describes the mechanism to allow IS-IS routing to quickly and accurately shift traffic away from either a point-to-point or multi-access LAN interface by signaling to an adjacent IS-IS neighbor with the metric towards itself during network maintenance or other operational events.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on July 12, 2018.

[1.](#) Introduction

The IS-IS [[ISO10589](#)] routing protocol has been widely used in Internet Service Provider IP/MPLS networks. Operational experience with the protocol, combined with ever increasing requirements for lossless operations have demonstrated some operational issues. This document describes the issues and a new mechanism for improving it.

[1.1.](#) Node and Link Isolation

IS-IS routing mechanism has the overload-bit, which can be used by operators to perform disruptive maintenance on the router. But in many operational maintenance cases, it is not necessary to displace all the traffic away from this node. It is useful to augment only a single link or LAN for the maintenance. More detailed descriptions

of the challenges can be found in [Appendix A](#) and [Appendix B](#) of this document.

[1.2.](#) Distributed Forwarding Planes

In a distributed forwarding platform, different forwarding line-cards may have interfaces and IS-IS connections to neighbor routers. If one of the line-card's software resets, it may take some time for the forwarding entries to be fully populated on this line-card, in particular if the router is a PE (Provider Edge) router in ISP's MPLS VPN. The IS-IS adjacency may be established with a neighbor router long before the entire BGP VPN prefixes are downloaded to the forwarding table. It is important to signal to the network not to use this particular IS-IS adjacency inbound to this router if possible. Temporarily pushing out the 'Reverse Metric' over this link to discourage the traffic into this line-card will help to reduce the traffic loss in the network. At the meantime, the remote PE routers will select a different set of PE routers for the BGP best path calculation or use a different link towards the same PE router on which another line-card is recovering.

[1.3.](#) Spine-Leaf Applications

In the IS-IS Spine-Leaf extension [[I-D.shen-isis-spine-leaf-ext](#)], the leaf nodes will perform equal-cost or unequal-cost load sharing towards all the spine nodes. In certain operational cases, for instance, when one of the backbone links on a spine node is congested, this spine node can push a higher metric towards the connected leaf nodes to reduce the transit traffic through this spine node or link.

[1.4.](#) LDP IGP Synchronization

In the [[RFC5443](#)], a mechanism is described to achieve LDP IGP synchronization by using the maximum link metric value on the interface. But in the case of a new IS-IS node joining the broadcast

network (LAN), it is not optimal to change all the nodes on the LAN to the maximum link metric value, as described in [[RFC6138](#)]. This Reverse Metric can be used in this case to discourage both outbound and inbound traffic without affecting the traffic of other existing IS-IS nodes on the LAN.

[1.5.](#) IS-IS Reverse Metric

This document proposes that the routing protocol itself be the transport mechanism to allow one IS-IS router to advertise a "reverse metric" in an IS-IS Hello (IIH) PDU to an adjacent node on a point-to-point or multi-access LAN link. This would allow the provisioning

Shen, et al.

Internet-Draft

IS-IS Reverse Metric

January 2018

to be performed only on a single node, set a "reverse metric" on a link and have traffic bidirectionally shift away from that link gracefully to alternate, viable paths.

This Reverse Metric mechanism is to be used for both point-to-point and multi-access LAN links. Unlike the point-to-point link, IS-IS protocol currently does not have a way to influence the traffic towards a particular node on LAN links. This proposal enables IS-IS routing the capability of altering traffic in both directions on either a point-to-point link or on a multi-access link of a node.

The metric value in the "reverse metric" TLV and the TE metric in the sub-TLV being advertised is an offset or relative metric to be added on top of the existing local link and TE metric value of the receiver.

[1.6.](#) Specification of Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

[2.](#) IS-IS Reverse Metric TLV

The Reverse Metric TLV is composed of a 1 octet field of Flags, a 3 octet field containing an IS-IS Metric, and a 1 octet Traffic Engineering (TE) sub-TLV length field representing the length of a variable number of Extended Intermediate System (IS) Reachability sub-TLVs. If the "sub-TLV len" is non-zero, then the Value field

MUST also contain data of 1 or more Extended IS Reachability sub-TLVs.

The Reverse Metric TLV is optional. The Reverse Metric TLV may be present in any IS-IS Hello PDU. A sender MUST only transmit a single Reverse Metric TLV in a IS-IS Hello PDU. If a received IS-IS Hello PDU contains more than one Reverse Metric TLV, an implementation SHOULD ignore all the Reverse Metric TLVs in this error condition.

Reverse Metric TLV

TYPE: TBD (be replaced by the value that IANA allocates)
 LENGTH: variable (5 - 255 octets)
 VALUE:

Flags (1 octet)
 Metric Offset (3 octets)
 sub-TLV length (1 octet)
 sub-TLV data (0 - 250 octets)

Figure 1: Flags

The Metric Offset field contains a 24-bit unsigned integer of an IS-IS metric that a neighbor SHOULD add to the existing, configured "default metric" of the IS-IS link. Refer to "Elements of Procedure", in [Section 3](#) for details on how an IS-IS router should process the Metric Offset field in a Reverse Metric TLV.

There is currently only two Flag bits defined.

W bit (0x01): The "Whole LAN" bit is only used in the context of multi-access LANs. When a Reverse Metric TLV is transmitted from a (non-DIS) node to the DIS, if the "Whole LAN" bit is set (1), then a DIS SHOULD add the received Metric Offset value in the Reverse Metric TLV to each node's existing "default metric" in the Pseudonode LSP. If the "Whole LAN" bit is not set (0), then a DIS SHOULD add the received Metric Offset value in the Reverse Metric TLV to the existing "default metric" in the Pseudonode LSP for the single node from whom the Reverse Metric TLV was received. Please refer to "Multi-Access LAN Procedures", in [Section 3.3](#), for additional details. The W bit MUST be unset when a Reverse Metric TLV is transmitted in a IIH PDU onto a point-to-point link to a neighbor, and the W bit MUST be ignored upon receiving on a point-to-point link.

U bit (0x02): The "Unreachable" bit is used by the IS-IS node to request the neighbor for setting the accumulated metric value to be limited to $(2^{24}-1)$. This "U" bit applies to both the default metric of Extended IS Reachability TLV and the TE default-metric sub-TLV of the link. This is only relevant to the IS-IS "wide" metric mode.

The "sub-TLV Len" value is non-zero when an IS-IS router wishes to signal that its neighbor alter parameters contained in the neighbor's Traffic Engineering "Extended IS Reachability TLV", as defined in

[\[RFC5305\]](#). This document defines that only the "Traffic Engineering Default Metric" sub-TLV, sub-TLV Type 18, may be sent toward neighbors in the Reverse Metric TLV, because that is used in Constrained Shortest Path First (CSPF) computations. Upon receiving this TE sub-TLV in a Reverse Metric TLV, a node SHOULD add the received TE default metric to its existing, configured TE default metric within its Extended IS Reachability TLV. Use of other sub-TLVs is outside the scope of this document. The "sub-TLV Len" value MUST be set to zero when an IS-IS router does not have TE sub-TLVs that it wishes to send to its IS-IS neighbor.

[3.](#) Elements of Procedure

[3.1.](#) Processing Changes to Default Metric

The Metric Offset field, in the Reverse Metric TLV, is a "default metric" that will either be in the range of 0 - 63 when a "narrow" IS-IS metric is used (IS Neighbors TLV, Pseudonode LSP) [[RFC1195](#)] or in the range of 0 - ($2^{24} - 2$) when a "wide" Traffic Engineering metric value is used, (Extended IS Reachability TLV) [[RFC5305](#)] [[RFC5817](#)]. It is important to use the same IS-IS metric mode in both ends of the link. On the receiving side of the 'reverse-metric' TLV, the accumulated value of configured metric and the reverse-metric needs to be limited to 63 in "narrow" metric mode and to ($2^{24} - 2$) in "wide" metric mode. This applies to both the default metric of Extended IS Reachability TLV and the TE default-metric sub-TLV in LSP or Pseudonode LSP with the "wide" metric mode case. If the "U" bit is present in the flag, the accumulated metric value is to be limited to ($2^{24} - 1$) instead, and this applies to both the normal link metric and TE metric in IS-IS "wide" metric mode.

If an IS-IS router is configured to originate a TE Default Metric sub-TLV for a link, but receives a Reverse Metric TLV from its neighbor that does not contain a TE Default Metric sub-TLV, then the IS-IS router MUST NOT change the value of its TE Default Metric sub-TLV for that link.

Routers MUST scan the Metric Offset value and TE sub-TLVs in all subsequently received Reverse Metric TLVs. If changes are observed by a receiver of the Reverse Metric TLV in the Metric Offset value or TE Default Metric sub-TLV value, the receiving router MUST update its advertised IS-IS default metric or Traffic Engineering parameters in the appropriate TLVs, recompute its SPF tree and flood new LSPs to other IS-IS routers.

[3.2.](#) Processing Changes to Default Metric for Multi-Topology IS-IS

The Reverse Metric TLV is applicable to Multi-Topology IS-IS (M-ISIS) [[RFC5120](#)] capable point-to-point links. If an IS-IS router is configured for M-ISIS it MUST send only a single Reverse Metric TLV in IIH PDUs toward its neighbor(s) on the designated link that is about to undergo maintenance. When an M-ISIS router receives a Reverse Metric TLV it MUST add the received Metric Offset value to

its default metric in all Extended IS Reachability TLVs for all topologies. If an M-ISIS router receives a Reverse Metric TLV with a TE Default Metric sub-TLV, then the M-ISIS router MUST add the received TE Default Metric value to each of its TE Default Metric sub-TLVs in all of its MT Intermediate Systems TLVs. If an M-ISIS router is configured to advertise TE Default Metric sub-TLVs for one or more topologies, but does not receive a TE Default Metric sub-TLV in a Reverse Metric TLV, then the M-ISIS router MUST add the value in Metric Offset field of the Reverse Metric TLV to each of the TE Default Metric sub-TLVs for all topologies. The M-ISIS should flood its newly updated MT IS TLVs and recompute its SPF/CSPF accordingly.

Multi-Topology IS-IS [[RFC5120](#)] specifies there is no change to construction of the Pseudonode LSP, regardless of the Multi-Topology capabilities of a multi-access LAN. If any MT capable node on the LAN advertises the Reverse Metric TLV to the DIS, the DIS should act according to the "Multi-Access LAN Procedures" in [Section 3.3](#) to update, as appropriate, the default metric contained in the Pseudonode LSP. If the DIS updates the default metric in and floods a new Pseudonode LSP, those default metric values will be applied to all topologies during Multi-Topology SPF calculations.

[3.3](#). Multi-Access LAN Procedures

On a Multi-Access LAN, only the DIS SHOULD act upon information contained in a received Reverse Metric TLV. All non-DIS nodes MUST silently ignore a received Reverse Metric TLV. The decision process of the routers on this LAN MUST follow the procedure in [section 7.2.8.2](#) of [[IS010589](#)], and use the "Two-way connectivity check" during the topology and route calculation.

The Reverse Metric TE sub-TLV also applies to the DIS. If a DIS is configured to apply TE over the link and it receives TE metric sub-TLV in Reverse Metric TLV, it should update TE Default Metric sub-TLV value of corresponding Extended IS Reachability TLV or insert new one if it was not present there.

In the case of multi-access LANs, the "W" Flags bit is used to signal from a non-DIS to the DIS whether to change the metric and optionally

a single node on the LAN, (the originator of the Reverse Metric TLV).

A non-DIS node, e.g.: Router B, attached to a multi-access LAN will send a Reverse Metric TLV with the W bit set to 0 to the DIS, when Router B wishes the DIS to add the Metric Offset value to the default metric contained in the Pseudonode LSP specific to just Router B. Other non-DIS nodes, i.e.: Routers C and D, may simultaneously send a Reverse Metric TLV with the W bit set to 0 to request the DIS add their own Metric Offset value to their default metric contained in the Pseudonode LSP. When the DIS receives a properly formatted Reverse Metric TLV with the W bit set to 0, the DIS MUST only add the default metric contained in its Pseudonode LSP for the specific neighbor that sent the Reverse Metric TLV.

As long as at least one IS-IS node on the LAN sending the signal to DIS with the W bit set, the DIS would add the metric value in the Reverse Metric TLV to all neighbor adjacencies in the Pseudonode LSP, regardless if some of the nodes on the LAN send the Reverse Metric TLV without the W bit set. The DIS MUST use the metric of the highest source MAC address of the node sending the TLV with the W bit set. The DIS MUST use the metric value towards the nodes which explicitly send the Reverse Metric TLV.

Local provisioning on the DIS to adjust the default metric(s) contained in the Pseudonode LSP MUST take precedence over received Reverse Metric TLVs. For instance, local policy of the DIS may be provisioned to ignore the W bit signaling on a LAN.

3.4. Point-To-Point Link Procedures

On a point-to-point link, there is already a "configured" IS-IS interface metric to be applied over the link towards the IS-IS neighbor.

When IS-IS receives the IIH PDU with the "Reverse Metric" on a point-to-point link and if the local policy allows the supporting of "Reverse Metric", it MUST add the metric value in the "Metric" field of the TLV to the locally configured interface metric value to be the metric for this IS-IS adjacency.

3.5. LDP/IGP Synchronization on LANs

As described in [[RFC6138](#)] when a new IS-IS node joins a broadcast network, it is unnecessary and sometimes even harmful to put IS-IS maximum link metric on all the nodes. [[RFC6138](#)] proposes a solution to have the new node not advertising the adjacency towards the pseudo-node when it is not in a "cut-edge" position.

With the introduction of Reverse Metric in this document, a simpler alternative solution to the above mentioned problem can be used. The Reverse Metric allows the new node on the LAN to have the inbound metric value to be the maximum and this puts the link of this new node in the last resort position without impacting the other IS-IS nodes on the same LAN.

Specifically, when IS-IS adjacencies are being established by the new node on the LAN, besides setting the maximum link metric value ($2^{24} - 2$) on the interface of the LAN for the LDP IGP synchronization as described in [RFC5443], it SHOULD advertise the maximum metric offset value in the Reverse Metric TLV in its IIH PDU to the LAN. It SHOULD continue this advertisement until it completes all the LDP label binding exchanges with all the neighbors over this LAN, either by receiving the LDP End-of-LIB [RFC5919] for all the sessions or by exceeding the provisioned timeout value on the node.

3.6. Operational Guidelines

A router MUST advertise a Reverse Metric TLV toward a neighbor only for the period during which it wants a neighbor to temporarily update its IS-IS metric or TE parameters towards it.

The use of Reverse Metric does not alter IS-IS metric parameters stored in a router's persistent provisioning database.

Routers that receive a Reverse Metric TLV MAY send a syslog message or SNMP trap, in order to assist in rapidly identifying the node in the network that is asserting an IS-IS metric or Traffic Engineering parameters different from that which is configured locally on the device.

It is RECOMMENDED that implementations provide a capability to disable any changes to a node's, or individual interfaces of the node, default metric or Traffic Engineering parameters based upon receiving properly formatted Reverse Metric TLVs.

4. Security Considerations

The enhancement in this document makes it possible for one IS-IS router to manipulate the IS-IS default metric or optionally Traffic Engineering parameters of adjacent IS-IS neighbors. Although IS-IS routers within a single Autonomous System nearly always reside under the control of a single administrative authority, it is highly RECOMMENDED that operators configure authentication of IS-IS PDUs to mitigate use of the Reverse Metric TLV as a potential attack vector,

particularly on multi-access LANs.

[5.](#) IANA Considerations

This document requests that IANA allocate from the IS-IS TLV Codepoints Registry a new TLV, referred to as the "Reverse Metric" TLV, possibly from the "Unassigned" range of 244-250, with the following attributes: IIH = y, LSP = n, SNP = n, Purge = n.

[Appendix A.](#) Node Isolation Challenges

On rare occasions it is necessary for an operator to perform disruptive network maintenance on an entire IS-IS router node, i.e.: major software upgrades, power/cooling augments, etc. In these cases, an operator will set the IS-IS Overload Bit (OL-bit) within the Link State Protocol Data Units (LSPs) of the IS-IS router about to undergo maintenance. The IS-IS router immediately floods the

updated LSPs to all IS-IS routers throughout the IS-IS domain. Upon receipt of the updated LSPs, all IS-IS routers recalculate their Shortest Path First (SPF) tree excluding IS-IS routers whose LSPs have the OL-bit set. This effectively removes the IS-IS router about to undergo maintenance from the topology, thus preventing it from forwarding any transit traffic during the maintenance period.

After the maintenance activity is completed, the operator resets the IS-IS Overload Bit within the LSPs of the original IS-IS router causing it to flood updated IS-IS LSPs throughout the IS-IS domain. All IS-IS routers recalculate their SPF tree and now include the original IS-IS router in their topology calculations, allowing it to be used for transit traffic again.

Isolating an entire IS-IS router from the topology can be especially disruptive due to the displacement of a large volume of traffic

through an entire IS-IS router to other, sub-optimal paths, (i.e.: those with significantly larger delay). Thus, in the majority of network maintenance scenarios, where only a single link or LAN needs to be augmented to increase its physical capacity or is experiencing an intermittent failure, it is much more common and desirable to gracefully remove just the targeted link or LAN from service, temporarily, so that the least amount of user-data traffic is affected while intrusive augment, diagnostic and/or replacement procedures are being executed.

[Appendix B](#). Link Isolation Challenges

Before network maintenance events are performed on individual physical links or LANs, operators substantially increase the IS-IS metric simultaneously on both devices attached to the same link or LAN. In doing so, the devices generate new Link State Protocol Data Units (LSPs) that are flooded throughout the network and cause all routers to gradually shift traffic onto alternate paths with very little, to no, disruption to in-flight communications by applications or end-users. When performed successfully, this allows the operator to confidently perform disruptive augmentation, fault diagnosis or repairs on a link without disturbing ongoing communications in the network.

The challenge with the above solution are as follows. First, it is

quite common to have routers with several hundred interfaces onboard and individual interfaces that are transferring several hundred Gigabits/second to Terabits/second of traffic. Thus, it is imperative that operators accurately identify the same point-to-point link on two, separate devices in order to increase (and, afterward, decrease) the IS-IS metric appropriately. Second, the aforementioned solution is very time consuming and even more error-prone to perform when its necessary to temporarily remove a multi-access LAN from the network topology. Specifically, the operator needs to configure ALL devices's that have interfaces attached to the multi-access LAN with an appropriately high IS-IS metric, (and then decrease the IS-IS metric to its original value afterward). Finally, with respect to multi-access LANs, there is currently no method to bidirectionally isolate only a single node's interface on the LAN when performed more fine-grained diagnosis and repairs to the multi-access LAN.

In theory, use of a Network Management System (NMS) could improve the accuracy of identifying the appropriate subset of routers attached to either a point-to-point link or a multi-access LAN as well as signaling from the NMS to those devices, using a network management protocol, to adjust the IS-IS metrics on the pertinent set of interfaces. The reality is that NMS are, to a very large extent, not used within Service Provider's networks for a variety of reasons. In

particular, NMS do not interoperate very well across different vendors or even separate platform families within the same vendor.

The risks of misidentifying one side of a point-to-point link or one or more interfaces attached to a multi-access LAN and subsequently increasing its IS-IS metric are potentially increased latency, jitter or packet loss. This is unacceptable given the necessary performance requirements for a variety of applications, the customer perception for near lossless operations and the associated, demanding Service Level Agreement's (SLAs) for all network services.
