**The I-JSON Message Format**  
**draft-ietf-json-i-json-05**

Abstract

I-JSON is a restricted profile of JSON designed to maximize interoperability and increase confidence that software can process it successfully with predictable results.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 21, 2015.

## [1.](#) Introduction

[RFC 7159](#) describes the JSON data interchange format, which is widely used in Internet protocols. For historical reasons, that specification allows the use of language idioms and text encoding patterns which are likely to lead to interoperability problems and software breakage, particularly when a program receiving JSON data uses automated software to map it into native programming-language structures or database records. [RFC 7159](#) describes practices which may be used to avoid these interoperability problems.

This document specifies I-JSON, short for "Internet JSON". The unit of definition is the "I-JSON message". I-JSON messages are also "JSON texts" as defined in [RFC 7159](#) but with certain extra constraints which enforce the good interoperability practices described in that specification.

### [1.1.](#) Terminology

The terms "object", "member", "array", "number", "name", and "string" in this document are to be interpreted as described in [RFC 7159](#) [[RFC7159](#)].

### [1.2.](#) Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

## **2. I-JSON Messages**

An I-JSON message is a JSON text, as defined by [RFC 7159](#).

### **2.1. Encoding and Characters**

I-JSON messages MUST be encoded using UTF-8 [[RFC3629](#)].

Object member names, and string values in arrays and object members, MUST NOT include code points which identify Surrogates or Noncharacters.

This applies both to characters encoded directly in UTF-8 and to those which are escaped; thus, `"\uDEAD"` is invalid because it is an unpaired surrogate, while `"\uD800\uDEAD"` would be legal.

### **2.2. Numbers**

Software which implements IEEE 754-2008 binary64 (double precision) numbers [[IEEE754](#)] is generally available and widely used.

Implementations which generate I-JSON messages cannot assume that receiving implementations can process numeric values with greater magnitude or precision than provided by those numbers. I-JSON messages SHOULD NOT include numbers which express greater magnitude or precision than an IEEE 754 double precision number provides, for example `1E400` or `3.141592653589793238462643383279`.

In particular, an I-JSON sender cannot expect a receiver to treat an integer whose absolute value is greater than `9007199254740991` (i.e., that is outside the range `[-(2**53)+1, (2**53)-1]`) as an exact value.

For applications which require the exact interchange of numbers with greater magnitude or precision (one example would be 64-bit integers), it is RECOMMENDED to encode them in JSON string values. This requires that the receiving program understand the intended semantic of the value.

### **2.3. Object constraints**

Objects in I-JSON messages MUST NOT have members with duplicate names. In this context, "duplicate" means that the names, after processing any escaped characters, are identical sequences of Unicode characters.

The order of object members in an I-JSON message does not change the meaning of an I-JSON message. A receiving implementation MAY treat two I-JSON messages as equivalent if they differ only in the order of the object members.

### **3. Software Behavior**

A major advantage of using I-JSON is that receivers can avoid ambiguous semantics in the JSON messages it receives. This allows receivers to reject or otherwise disregard messages which do not conform to the requirements in this document for I-JSON messages. Protocols that use I-JSON message can be written so that receiving implementation are required to reject (or, as in the case of security protocols, not trust) messages that do not satisfy the constraints of I-JSON.

Designers of protocols which use I-JSON messages SHOULD provide a way, in this case, for the receiver of the erroneous data to signal the problem to the sender.

### **4. Protocol-design Recommendations**

I-JSON is designed for use in Internet protocols. The following recommendations apply to the use of I-JSON in such protocols.

#### **4.1. Top-level Constructs**

An I-JSON message can be any JSON value. However, there are software implementations, coded to the older [\[RFC4627\]](#) specification, which only accept JSON objects or JSON arrays at the top level of JSON texts. For maximum interoperability with such implementations, protocol designers SHOULD NOT use top-level JSON texts which are neither objects nor arrays.

#### **4.2. Must-ignore Policy**

It is frequently the case that changes to protocols are required after they have been put in production. Protocols which allow the introduction of new protocol elements in a way that does not disrupt the operation of existing software have proven advantageous in practice.

This can be referred to as a "Must-Ignore" policy, meaning that when an implementation encounters a protocol element which it does not recognize, it should treat the rest of the protocol transaction as if the new element simply did not appear, and in particular MUST NOT treat this as an error condition. The converse "Must-Understand" policy does not tolerate the introduction of new protocol elements, and while this has proven necessary in certain protocol designs, in general it has been found to be overly restrictive and brittle.

A good way to support the use of Must-Ignore in I-JSON protocol designs is to require that top-level protocol elements must be JSON

objects, and to specify that members whose names are unrecognized MUST be ignored.

#### **4.3. Time and Date Handling**

Protocols often contain data items which are designed to contain timestamps or time durations. It is RECOMMENDED that all such data items be expressed as string values in in ISO 8601 format, as specified in [RFC3339], with the additional restriction that uppercase rather than lowercase letters be used. It is also RECOMMENDED that all data items containing time durations conform to the "duration" production in [Appendix A of RFC3339](#), with the same additional restriction.

#### **4.4. Binary Data**

When it is required that an I-JSON protocol element contain arbitrary binary data, it is RECOMMENDED that this data be encoded in a string value in base64url; see [Section 5 of \[RFC4648\]](#).

### **5. Acknowledgements**

I-JSON is entirely dependent on the design of JSON, largely due to Douglas Crockford. The specifics were strongly influenced by the contributors to the design of [RFC 7159](#) on the IETF JSON Working Group.

### **6. Security Considerations**

All the security considerations which apply to JSON (see [RFC 7159](#)) apply to I-JSON. There are no additional security considerations specific to I-JSON.
