SPAKE Pre-Authentication

Abstract

This document defines a new pre-authentication mechanism for the Kerberos protocol. The mechanism uses a password-authenticated key exchange to prevent brute-force password attacks, and may optionally incorporate a second factor.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 10 December 2022.

1. Introduction

The Kerberos protocol [[RFC4120](#)] commonly uses password-derived long-term keys to secure the initial authentication exchange between a Kerberos client and a Key Distribution Center (KDC). As noted in Section 10 of [[RFC4120](#)], an attacker can perform an offline dictionary attack against the password, either by initiating an authentication exchange to a principal for which the KDC does not require pre-authentication, or after eavesdropping on a legitimate authentication exchange that uses encrypted timestamp pre-authentication (Section 5.2.7.2 of [[RFC4120](#)]).

This document defines a pre-authentication mechanism that authenticates using long-term keys but is resistant to offline dictionary attacks. The mechanism additionally enables the use of second factor authentication without the need for a separately-established secure channel, by leveraging the trust relationship established by the shared long-term key.

1.1. Properties of PAKE

Password authenticated key exchange (PAKE) algorithms [[RFC8125](#)] provide several properties which defend against offline dictionary attacks and make them ideal for use in a Kerberos pre-authentication mechanism.

1. Each side of the exchange contributes entropy.
2. Passive attackers cannot determine the shared key.
3. Active attackers cannot perform a man-in-the-middle attack.

These properties of PAKE allow us to establish high-entropy encryption keys resistant to offline brute force attack, even when the passwords used are weak (low-entropy).

1.2. PAKE Algorithm Selection

The SPAKE algorithm (defined in [[SPAKE](#)]) works by encrypting the public keys of a Diffie-Hellman key exchange with a shared secret. SPAKE was selected for this pre-authentication mechanism for the following properties:

1. Because SPAKE's encryption method ensures that the result is a member of the underlying group, it can be used with elliptic

curve cryptography, which is believed to provide equivalent security levels to finite-field DH key exchange at much smaller key sizes.

2. It can compute the shared key after just one message from each party, minimizing the need for additional round trips and state.
3. It requires a small number of group operations, and can therefore be implemented simply and efficiently.

1.3. PAKE and Two-Factor Authentication

Using PAKE in a pre-authentication mechanism also has another benefit when used as a component of two-factor authentication (2FA). 2FA methods often require the secure transfer of plaintext material to the KDC for verification. This includes one-time passwords, challenge/response signatures and biometric data. Encrypting this data using the long-term secret results in packets that are vulnerable to offline brute-force attack on the password, using either an authentication tag or statistical properties of the 2FA credentials to determine whether a password guess is correct.

In the OTP pre-authentication [[RFC6560](#)] specification, this problem is mitigated by using flexible authentication secure tunneling (FAST) (Section 5.4 of [[RFC6113](#)]), which uses a secondary trust relationship to create a secure encryption channel within which pre-authentication data can be sent. However, the requirement for a secondary trust relationship has proven to be cumbersome to deploy and often introduces third parties into the trust chain (such as certification authorities). These requirements make it difficult to enable FAST without manual configuration of client hosts. SPAKE pre-authentication, in contrast, can create a secure encryption channel implicitly, using the key exchange to negotiate a high-entropy encryption key. This key can then be used to securely encrypt 2FA plaintext data without the need for a secondary trust relationship. Further, if the second factor verifiers are sent at the same time as the first factor verifier, and the KDC is careful to prevent timing attacks, then an online brute-force attack cannot be used to attack the factors separately.

For these reasons, this document departs from the advice given in Section 1 of [RFC 6113](#) [[RFC6113](#)] which states that "Mechanism designers should design FAST factors, instead of new pre-authentication mechanisms outside of FAST." However, this pre-authentication mechanism does not intend to replace FAST, and may be used with it to further conceal the metadata of the Kerberos messages.

1.4. SPAKE Overview

The SPAKE algorithm can be broadly described in a series of four steps:

1. Calculation and exchange of the public key
2. Calculation of the shared secret (K)
3. Derivation of an encryption key (K')
4. Verification of the derived encryption key (K')

In this mechanism, key verification happens implicitly by a successful decryption of the 2FA data, or of a placeholder value when no second factor is required. This mechanism uses a tailored method of deriving encryption keys from the calculated shared secret K, for several reasons: to fit within the framework of [\[RFC3961\]](#), to ensure negotiation integrity using a transcript hash, to derive different keys for each use, and to bind the KDC-REQ-BODY to the pre-authentication exchange.

2. Document Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [\[RFC2119\]](#) [\[RFC8174\]](#) when, and only when, they appear in all capitals, as shown here.

This document refers to numerous terms and protocol messages defined in [\[RFC4120\]](#).

The terms "encryption type", "key generation seed length", and "random-to-key" are defined in [\[RFC3961\]](#).

The terms "FAST", "PA-FX-COOKIE", "KDC_ERR_PREAUTH_EXPIRED", "KDC_ERR_MORE_PREAUTH_DATA_REQUIRED", "KDC_ERR_PREAUTH_FAILED", "pre-authentication facility", and "authentication set" are defined in [\[RFC6113\]](#).

The [\[SPAKE\]](#) paper defines SPAKE as a family of two key exchange algorithms differing only in derivation of the final key. This mechanism uses a derivation similar to the second algorithm (SPAKE2) with differences in detail. For simplicity, this document refers to the algorithm as "SPAKE".

The terms "ASN.1" and "DER" are defined in [\[CCITT.X680.2002\]](#) and [\[CCITT.X690.2002\]](#) respectively.

When discussing operations within algebraic groups, this document uses additive notation (as described in Section 2.2 of [[RFC6090](#)]). Group elements are denoted with uppercase letters, while scalar multiplier values are denoted with lowercase letters.

3. Prerequisites

3.1. PA-ETYPE-INFO2

This mechanism requires the initial KDC pre-authentication state to contain a singular reply key. Therefore, a KDC which offers SPAKE pre-authentication as a stand-alone mechanism MUST supply a PA-ETYPE-INFO2 value containing a single ETYPE-INFO2-ENTRY, following the guidance in Section 2.1 of [[RFC6113](#)]. PA-ETYPE-INFO2 is specified in Section 5.2.7.5 of [[RFC4120](#)].

3.2. Cookie Support

KDCs which implement SPAKE pre-authentication MUST have some secure mechanism for retaining state between AS-REQs. For stateless KDC implementations, this method will most commonly be an encrypted PA-FX-COOKIE. Clients which implement SPAKE pre-authentication MUST support PA-FX-COOKIE, as described in Section 5.2 of [[RFC6113](#)].

3.3. More Pre-Authentication Data Required

Both KDCs and clients which implement SPAKE pre-authentication MUST support the use of KDC_ERR_MORE_PREAUTH_DATA_REQUIRED, as described in Section 5.2 of [[RFC6113](#)].

4. SPAKE Pre-Authentication Message Protocol

This mechanism uses the reply key and provides the Client Authentication and Strengthening Reply Key pre-authentication facilities (Section 3 of [[RFC6113](#)]). When the mechanism completes successfully, the client will have proved knowledge of the original reply key and possibly a second factor, and the reply key will be strengthened to a more uniform distribution based on the PAKE exchange. This mechanism also ensures the integrity of the KDC-REQ-BODY contents. This mechanism can be used in an authentication set; no pa-hint value is required or defined.

This mechanism negotiates a choice of group for the SPAKE algorithm. Groups are defined in the IANA "Kerberos SPAKE Groups" registry created by this document. Each group definition specifies an associated hash function, which will be used for transcript protection and key derivation. Clients and KDCs MUST implement the edwards25519 group, but MAY choose not to offer or accept it by default.

This section will describe the flow of messages when performing SPAKE pre-authentication. We will begin by explaining the most verbose version of the protocol which all implementations MUST support. Then we will describe several optional optimizations to reduce round-trips.

Mechanism messages are communicated using PA-DATA elements within the padata field of KDC-REQ messages or within the METHOD-DATA in the e-data field of KRB-ERROR messages. All PA-DATA elements for this mechanism MUST use the following padata-type:

PA-SPAKE 151

The padata-value for all PA-SPAKE PA-DATA values MUST be empty or contain a DER encoding for the ASN.1 type PA-SPAKE.

```
PA-SPAKE ::= CHOICE {  
    support      [0] SPAKESupport,  
    challenge    [1] SPAKEChallenge,  
    response     [2] SPAKEResponse,  
    encdata      [3] EncryptedData,  
    ...  
}
```

4.1. First Pass

The SPAKE pre-authentication exchange begins when the client sends an initial authentication service request (AS-REQ) without pre-authentication data. Upon receipt of this AS-REQ, a KDC which requires pre-authentication and supports SPAKE SHOULD reply with a KDC_ERR_PREAUTH_REQUIRED error, with METHOD-DATA containing an empty PA-SPAKE PA-DATA element (possibly in addition to other PA-DATA elements). This message indicates to the client that the KDC supports SPAKE pre-authentication.

4.2. Second Pass

Once the client knows that the KDC supports SPAKE pre-authentication and the client desires to use it, the client will generate a new AS-REQ message containing a PA-SPAKE PA-DATA element using the support choice. This message indicates to the KDC which groups the client prefers for the SPAKE operation. The group numbers are defined in the IANA "Kerberos SPAKE Groups" registry created by this document. The groups sequence is ordered from the most preferred group to the least preferred group.

```

SPAKESupport ::= SEQUENCE {
    groups      [0] SEQUENCE (SIZE(1..MAX)) OF Int32,
    ...
}

```

Upon receipt of the support message, the KDC will select a group. The KDC SHOULD choose a group from the groups provided by the support message. However, if the support message does not contain any group that is supported by the KDC, the KDC MAY select another group in hopes that the client might support it. Otherwise, the KDC MUST respond with a KDC_ERR_PREAUTH_FAILED error.

The group selection determines the group order, which shall be a large prime p multiplied by a small cofactor h (possibly 1), as well as a generator P of a prime-order subgroup and two masking points M and N . The KDC selects a random integer x in the range $0 \leq x < h \cdot p$, which MUST be divisible by h . The KDC computes a public key $T = x \cdot P + w \cdot M$, where w is computed from the initial reply key according to [Section 5](#).

The KDC will reply to the client with a KDC_ERR_MORE_PREAUTH_DATA_REQUIRED error containing a PA-SPAKE PA-DATA element using the challenge choice.

```

SPAKEChallenge ::= SEQUENCE {
    group      [0] Int32,
    pubkey     [1] OCTET STRING,
    factors    [2] SEQUENCE (SIZE(1..MAX)) OF SPAKESecondFactor,
    ...
}

```

The group field indicates the KDC-selected group used for all SPAKE calculations as defined in the IANA "Kerberos SPAKE Groups" registry created by this document.

The pubkey field indicates the KDC's public key T , serialized according to [Section 5](#).

The factors field contains an unordered list of second factors which can be used to complete the authentication. Each second factor is represented by a SPAKESecondFactor.

```

SPAKESecondFactor ::= SEQUENCE {
    type      [0] Int32,
    data      [1] OCTET STRING OPTIONAL
}

```

The type field is a unique integer which identifies the second factor type. The factors field of SPAKEChallenge MUST NOT contain more than one SPAKESecondFactor with the same type value.

The data field contains optional challenge data. The contents in this field will depend upon the second factor type chosen. Note that this challenge is initially transmitted as unauthenticated plaintext; see [Section 10.2](#).

The client and KDC will each initialize a transcript hash ([Section 6](#)) using the hash function associated with the chosen group, and update it with the concatenation of the DER-encoded PA-SPAKE messages sent by the client and the KDC.

4.3. Third Pass

Upon receipt of the challenge message, the client observes which group was selected by the KDC and deserializes the KDC's public key T . The client selects a random integer y in the range $0 \leq x < h \cdot p$, which MUST be divisible by h . The client computes a public key $S = y \cdot P + w \cdot N$, where w is computed from the initial reply key according to [Section 5](#). The client computes a shared group element $K = y \cdot (T - w \cdot M)$.

The client will then choose one of the second factor types listed in the factors field of the challenge message and gather whatever data is required for the chosen second factor type, possibly using the associated challenge data. Finally, the client will send an AS-REQ containing a PA-SPAKE PA-DATA element using the response choice.

```
SPAKEResponse ::= SEQUENCE {  
    pubkey      [0] OCTET STRING,  
    factor      [1] EncryptedData, -- SPAKESecondFactor  
    ...  
}
```

The client and KDC will update the transcript hash with the pubkey value, and use the resulting hash for all encryption key derivations.

The pubkey field indicates the client's public key S , serialized according to [Section 5](#).

The factor field indicates the client's chosen second factor data. The key for this field is $K'[1]$ as specified in [Section 7](#). The kvno field of the EncryptedData sequence is omitted. The key usage number

for the encryption is KEY_USAGE_SPAKE. The plain text inside the EncryptedData is an encoding of SPAKESecondFactor. Once decoded, the SPAKESecondFactor contains the type of the second factor and any optional data used. The contents of the data field will depend on the second factor type chosen. The client MUST NOT send a response containing a second factor type which was not listed in the factors field of the challenge message.

When the KDC receives the response message from the client, it deserializes the client's public key S , and computes the shared group element $K = x \cdot (S - w \cdot N)$. The KDC derives $K'[1]$ and decrypts the factors field. If decryption is successful, the first factor is successfully validated. The KDC then validates the second factor. If either factor fails to validate, the KDC SHOULD respond with a KDC_ERR_PREAUTH_FAILED error.

If validation of the second factor requires further round-trips, the KDC MUST reply to the client with KDC_ERR_MORE_PREAUTH_DATA_REQUIRED containing a PA-SPAKE PA-DATA element using the encdata choice. The kvno field of the EncryptedData sequence is omitted. The key for the EncryptedData value is $K'[2]$ as specified in [Section 7](#), and the key usage number is KEY_USAGE_SPAKE. The plain text of this message contains a DER-encoded SPAKESecondFactor message. As before, the type field of this message will contain the second factor type, and the data field will optionally contain second factor type specific data.

KEY_USAGE_SPAKE 65

4.4. Subsequent Passes

Any number of additional round trips may occur using the encdata choice. The contents of the plaintexts are specific to the second factor type. If a client receives a PA-SPAKE PA-DATA element using the encdata choice from the KDC, it MUST reply with a subsequent AS-REQ with a PA-SPAKE PA-DATA using the encdata choice, or abort the AS exchange.

The key for client-originated encdata messages in subsequent passes is $K'[3]$ as specified in [Section 7](#) for the first subsequent pass, $K'[5]$ for the second, and so on. The key for KDC-originated encdata messages is $K'[4]$ for the first subsequent pass, $K'[6]$ for the second, and so on.

4.5. Reply Key Strengthening

When the KDC has successfully validated both factors, the reply key is strengthened and the mechanism is complete. To strengthen the reply key, the client and KDC replace it with $K'[0]$ as specified in [Section 7](#). The KDC then replies with a KDC-REP message, or continues

on to the next mechanism in the authentication set. There is no final PA-SPAKE PA-DATA message from the KDC to the client.

Reply key strengthening occurs only once at the end of the exchange. The client and KDC MUST use the initial reply key as the base key for all $K'[n]$ derivations.

4.6. Optimizations

The full protocol has two possible optimizations.

First, the KDC MAY reply to the initial AS-REQ (containing no pre-authentication data) with a PA-SPAKE PA-DATA element using the challenge choice, instead of an empty padata-value. In this case, the KDC optimistically selects a group which the client may not support. If the group chosen by the challenge message is supported by the client, the client MUST skip to the third pass by issuing an AS-REQ with a PA-SPAKE message using the response choice. In this case no SPAKESupport message is sent by the client, so the first update to the transcript hash contains only the KDC's optimistic challenge. If the KDC's chosen group is not supported by the client, the client MUST continue to the second pass. In this case both the client and KDC MUST reinitialize the transcript hash for the client's support message. Clients MUST support this optimization.

Second, clients MAY skip the first pass and send an AS-REQ with a PA-SPAKE PA-DATA element using the support choice. If the KDC accepts the support message and generates a challenge, it MUST include a PA-ETYPE-INFO2 value within the METHOD-DATA of the KDC_ERR_MORE_PREAUTH_DATA_REQUIRED error response, as the client may not otherwise be able to compute the initial reply key. If the KDC cannot continue with SPAKE (either because initial reply key type is incompatible with SPAKE or because it does not support any of the client's groups) but can offer other pre-authentication mechanisms, it MUST respond with a KDC_ERR_PREAUTH_FAILED error containing METHOD-DATA for the available mechanisms. A client supporting this optimization MUST continue after a KDC_ERR_PREAUTH_FAILED error as described in Section 2 of [\[RFC6113\]](#). KDCs MUST support this optimization.

5. SPAKE Parameters and Conversions

Group elements are converted to and from octet strings using the serialization method defined in the IANA "Kerberos SPAKE Groups" registry created by this document.

The SPAKE algorithm requires constants M and N for each group. These constants are defined in the IANA "Kerberos SPAKE Groups" registry created by this document.

The SPAKE algorithm requires a shared secret input w to be used as a scalar multiplier. This value **MUST** be produced from the initial reply key as follows:

1. Determine the length of the multiplier octet string as defined in the IANA "Kerberos SPAKE Groups" registry created by this document.
2. Compose a pepper string by concatenating the string "SPAKEsecret" and the group number as a big-endian four-byte two's complement binary number.
3. Produce an octet string of the required length using $\text{PRF}^+(K, \text{pepper})$, where K is the initial reply key and PRF^+ is defined in Section 5.1 of [[RFC6113](#)].
4. Convert the octet string to a multiplier scalar using the multiplier conversion method defined in the IANA "Kerberos SPAKE Groups" registry created by this document.

The KDC chooses a secret scalar value x and the client chooses a secret scalar value y . As required by the SPAKE algorithm, these values are chosen randomly and uniformly. The KDC and client **MUST NOT** reuse x or y values for authentications involving different initial reply keys (see [Section 10.4](#)).

6. Transcript Hash

The transcript hash is an octet string of length equal to the output length of the hash function associated with the selected group. The initial value consists of all bits set to zero.

When the transcript hash is updated with an octet string input, the new value is the hash function computed over the concatenation of the old value and the input.

In the normal message flow or with the second optimization described in [Section 4.6](#), the transcript hash is first updated with the concatenation of the client's support message and the KDC's challenge, and then updated a second time with the client's pubkey value. It therefore incorporates the client's supported groups, the KDC's chosen group, the KDC's initial second-factor messages, and the client and KDC public values. Once the transcript hash is finalized, it is used without change for all key derivations ([Section 7](#)). In particular, encrypted second-factor messages are not included in the transcript hash.

If the first optimization described in [Section 4.6](#) is used successfully, the transcript hash is updated first with the KDC's challenge message, and second with the client's pubkey value.

If first optimization is used unsuccessfully (i.e. the client does not accept the KDC's selected group), the transcript hash is computed as in the normal message flow, without including the KDC's optimistic challenge.

7. Key Derivation

Implementations MUST NOT use the shared group element (denoted by K) directly for any cryptographic operation. Instead, the SPAKE result is used to derive keys $K'[n]$ as defined in this section.

First, compute the hash function associated with the selected group over the concatenation of the following values:

- *The fixed string "SPAKEkey".
- *The group number as a big-endian four-byte two's complement binary number.
- *The encryption type of the initial reply key as a big-endian four-byte two's complement binary number.
- *The PRF+ output used to compute the initial secret input w as specified in [Section 5](#).
- *The SPAKE result K , converted to an octet string as specified in [Section 5](#).
- *The transcript hash.
- *The KDC-REQ-BODY encoding for the request being sent or responded to. Within a FAST channel, the inner KDC-REQ-BODY encoding MUST be used.
- *The value n as a big-endian four-byte unsigned binary number.
- *A single-byte block counter, with the initial value $0x01$.

If the hash output is too small for the encryption type's key generation seed length, the block counter value is incremented and the hash function re-computed to produce as many blocks as are required. The result is truncated to the key generation seed length, and the random-to-key function is used to produce an intermediate key with the same encryption type as the initial reply key.

The key $K'[n]$ has the same encryption type as the initial reply key, and has the value $KRB-FX-CF2(\text{initial-reply-key}, \text{intermediate-key}, \text{"SPAKE"}, \text{"keyderiv"})$, where $KRB-FX-CF2$ is defined in Section 5.1 of [\[RFC6113\]](#).

8. Second Factor Types

This document defines one second factor type:

SF-NONE 1

This second factor type indicates that no second factor is used. Whenever a SPAKESecondFactor is used with SF-NONE, the data field MUST be omitted. The SF-NONE second factor always successfully validates.

9. Hint for Authentication Sets

If a KDC offers SPAKE pre-authentication as part of an authentication set (Section 5.3 of [[RFC6113](#)]), it MAY provide a pa-hint value containing the DER encoding of the ASN.1 type PA-SPAKE-HINT, to help the client determine whether SPAKE pre-authentication is likely to succeed if the authentication set is chosen.

```
PA-SPAKE-HINT ::= SEQUENCE {  
    groups      [0] SEQUENCE (SIZE(1..MAX)) OF Int32,  
    factors     [1] SEQUENCE (SIZE(1..MAX)) OF SPAKESecondFactor  
}
```

The groups field indicates the KDC's supported groups. The factors field indicates the KDC's supported second factors. The KDC MAY omit the data field of values in the factors list.

A KDC MUST NOT include a PA-SPAKE-HINT message directly in a pa-value field; hints must only be provided within authentication sets. A KDC SHOULD include a hint if SPAKE pre-authentication is offered as the second or later element of an authentication set.

The PA-SPAKE-HINT message is not part of the transcript, and does not replace any part of the SPAKE message flow.

10. Security Considerations

10.1. SPAKE Computations

The deserialized public keys S and T MUST be verified to be elements of the group, to prevent invalid curve attacks. It is not necessary to verify that they are members of the prime-order subgroup, as the computation of K by both parties involves a multiplication by the cofactor h.

The aforementioned cofactor multiplication is accomplished by choosing private scalars x and y which are divisible by the

cofactor. If the client or KDC chooses a scalar which might not be divisible by the cofactor, an attacker might be able to coerce values of K which are not members of the prime-order subgroup, and deduce a limited amount of information about w from the order of K .

The scalars x and y MUST be chosen uniformly, and must not be reused for different initial reply keys. If an x or y value is reused for pre-authentications involving two different initial reply keys, an attacker who observes both authentications and knows one of the initial reply keys can conduct an offline dictionary attack to recover the other one.

The M and N values for a group MUST NOT have known discrete logs. An attacker who knows the discrete log of M or N can perform an offline dictionary attack on passwords. It is therefore important to demonstrate that the M and N values for each group were computed without multiplying a known value by the generator P .

10.2. Unauthenticated Plaintext

This mechanism includes unauthenticated plaintext in the support and challenge messages. Beginning with the third pass, the integrity of this plaintext is ensured by incorporating the transcript hash into the derivation of the final reply key and second factor encryption keys. Downgrade attacks on support and challenge messages will result in the client and KDC deriving different reply keys and EncryptedData keys. The KDC-REQ-BODY contents are also incorporated into key derivation, ensuring their integrity. The unauthenticated plaintext in the KDC-REP message is not protected by this mechanism.

Unless FAST is used, the factors field of a challenge message is not integrity-protected until the response is verified. Second factor types MUST account for this when specifying the semantics of the data field. Second factor data in the challenge should not be included in user prompts, as it could be modified by an attacker to contain misleading or offensive information.

Unless FAST is used, the factors field of a challenge message is visible to an attacker, who can use it to determine whether a second factor is required for the client.

Subsequent factor data, including the data in the response, are encrypted in a derivative of the shared secret K . Therefore, it is not possible to exploit the untrustworthiness of the challenge to turn the client into an encryption or signing oracle for the second factor credentials, unless the attacker knows the client's long-term key.

Unless FAST is used, any PA-SPAKE-HINT messages included when SPAKE is advertised in authentication sets are unauthenticated, and are

not protected by the transcript hash. Since hints do not replace any part of the message flow, manipulation of hint messages can only affect the client's decision to use or not use an authentication set, which could more easily be accomplished by removing authentication sets entirely.

10.3. Side Channels

An implementation of this pre-authentication mechanism can have the property of indistinguishability, meaning that an attacker who guesses a long-term key and a second factor value cannot determine whether one of the factors was correct unless both are correct. Indistinguishability is only maintained if the second factor can be validated solely based on the data in the response; the use of additional round trips will reveal to the attacker whether the long-term key is correct. Indistinguishability also requires that there are no side channels. When processing a response message, whether or not the KDC successfully decrypts the factor field, it must reply with the same error fields, take the same amount of time, and make the same observable communications to other servers.

Both the size of the EncryptedData and the number of EncryptedData messages used for second-factor data (including the factor field of the SPAKEResponse message and messages using the encdata PA-SPAKE choice) may reveal information about the second factor used in an authentication. Care should be taken to keep second factor messages as small and as few as possible.

Any side channels in the creation of the shared secret input w , or in the multiplications wM and wN , could allow an attacker to recover the client long-term key. Implementations **MUST** take care to avoid side channels, particularly timing channels. Generation of the secret scalar values x and y need not take constant time, but the amount of time taken **MUST NOT** provide information about the resulting value.

The conversion of the scalar multiplier for the SPAKE w parameter may produce a multiplier that is larger than the order of the group. Some group implementations may be unable to handle such a multiplier. Others may silently accept such a multiplier, but proceed to perform multiplication that is not constant time. This is only a minor risk in most commonly-used groups, but is a more serious risk for P-521 due to the extra seven high bits in the input octet string. A common solution to this problem is achieved by reducing the multiplier modulo the group order, taking care to ensure constant time operation.

10.4. KDC State

A stateless KDC implementation generally must use a PA-FX-COOKIE value to remember its private scalar value x and the transcript hash. The KDC **MUST** maintain confidentiality and integrity of the cookie value, perhaps by encrypting it in a key known only to the realm's KDCs. Cookie values may be replayed by attackers, perhaps splicing them into different SPAKE exchanges. The KDC **SHOULD** limit the time window of replays using a timestamp, and **SHOULD** prevent cookie values from being applied to other pre-authentication mechanisms or other client principals. Within the validity period of a cookie, an attacker can replay the final message of a pre-authentication exchange to any of the realm's KDCs and make it appear that the client has authenticated.

This pre-authentication mechanism is not designed to provide forward secrecy. Nevertheless, some measure of forward secrecy may result depending on implementation choices. A passive attacker who determines the client long-term key after the exchange generally will not be able to recover the ticket session key; however, an attacker who also determines the PA-FX-COOKIE encryption key (if the KDC uses an encrypted cookie) will be able to recover the ticket session key. The KDC can mitigate this risk by periodically rotating the cookie encryption key. If the KDC or client retains the x or y value for reuse with the same client long-term key, an attacker who recovers the x or y value and the long-term key will be able to recover the ticket session key.

10.5. Dictionary Attacks

Although this pre-authentication mechanism is designed to prevent an offline dictionary attack by an active attacker posing as the KDC, such an attacker can attempt to downgrade the client to encrypted timestamp. Client implementations **SHOULD** provide a configuration option to enable or disable encrypted timestamp on a per-realm basis to mitigate this attack.

If the user enters the wrong password, the client might fall back to encrypted timestamp after receiving a KDC_ERR_PREAUTH_FAILED error from the KDC, if encrypted timestamp is offered by the KDC and not disabled by client configuration. This fallback will enable a passive attacker to mount an offline dictionary attack against the incorrect password, which may be similar to the correct password. Client implementations **SHOULD** assume that encrypted timestamp and encrypted challenge are unlikely to succeed if SPAKE pre-authentication fails in the second pass and SF-NONE was used.

Like any other pre-authentication mechanism using the client long-term key, this pre-authentication mechanism does not prevent online

password guessing attacks. The KDC is made aware of unsuccessful guesses, and can apply facilities such as rate limiting to mitigate the risk of online attacks.

10.6. Brute Force Attacks

The selected group's resistance to offline brute-force attacks may not correspond to the size of the reply key. For performance reasons, a KDC MAY select a group whose brute-force work factor is less than the reply key length. A passive attacker who solves the group discrete logarithm problem after the exchange will be able to conduct an offline attack against the client long-term key. Although the use of password policies and costly, salted string-to-key functions may increase the cost of such an attack, the resulting cost will likely not be higher than the cost of solving the group discrete logarithm.

10.7. Denial of Service Attacks

Elliptic curve group operations are more computationally expensive than secret-key operations. As a result, the use of this mechanism may affect the KDC's performance under normal load and its resistance to denial of service attacks.

10.8. Reflection Attacks

The encdata choice of PA-SPAKE can be used in either direction, and the factor-specific plaintext does not necessarily indicate a direction. However, each encdata message is encrypted using a derived key $K'[n]$, with client-originated messages using only odd values of n and KDC-originated messages using only even values. An attempted reflection attack would therefore result in a failed decryption.

10.9. Reply-Key Encryption Type

This mechanism does not upgrade the encryption type of the initial reply key, and relies on that encryption type for confidentiality, integrity, and pseudo-random functions. If the client long-term key uses a weak encryption type, an attacker might be able to subvert the exchange, and the replaced reply key will also be of the same weak encryption type.

10.10. KDC Authentication

This mechanism does not directly provide the KDC Authentication pre-authentication facility, because it does not send a key confirmation from the KDC to the client. When used as a stand-alone mechanism, the traditional KDC authentication provided by the KDC-REP enc-part still applies.

11. Assigned Constants

The following key usage values are assigned for this mechanism:

KEY_USAGE_SPAKE 65

12. IANA Considerations

IANA has assigned the following number for PA-SPAKE in the "Pre-authentication and Typed Data" registry:

Type	Value	Reference
PA-SPAKE	151	[this document]

Table 1

This document establishes two registries with the following procedure, in accordance with [[RFC8126](#)]:

Registry entries are to be evaluated using the Specification Required method. All specifications must be published prior to entry inclusion in the registry. Once published, they can be submitted directly to the krb5-spake-review@ietf.org mailing list, where there will be a three-week long review period by Designated Experts.

The Designated Experts ensure that the specification is publicly available. It is sufficient to have an Internet-Draft (that is posted and never published as an RFC) or a document from another standards body, industry consortium, university site, etc. The Designated Experts may provide additional in-depth reviews, but their approval should not be taken as endorsement of the specification.

Prior to the end of the review period, the Designated Experts must approve or deny the request. This decision is conveyed to both IANA and the submitter. Since the mailing list archives are not public, it should include both a reasonably detailed explanation in the case of a denial as well as whether the request can be resubmitted.

IANA must only accept registry updates from the designated experts and should direct all requests for registration to the review mailing list.

12.1. Kerberos Second Factor Types

This section species the IANA "Kerberos Second Factor Types" registry. This registry records the number, name, and reference for each second factor protocol.

12.1.1. Registration Template

ID Number:

This is a value that uniquely identifies this entry. It is a signed integer in range -2147483648 to 2147483647, inclusive. Positive values must be assigned only for algorithms specified in accordance with these rules for use with Kerberos and related protocols. Negative values should be used for private and experimental algorithms only. Zero is reserved and must not be assigned. Values should be assigned in increasing order.

Name: Brief, unique, human-readable name for this algorithm.

Reference: URI or otherwise unique identifier for where the details of this algorithm can be found. It should be as specific as reasonably possible.

12.1.2. Initial Registry Contents

ID Number: 1

Name: SF-NONE

Reference: [this document]

12.2. Kerberos SPAKE Groups

This section specifies the IANA "Kerberos SPAKE Groups" registry. This registry records the number, name, specification, serialization, multiplier length, multiplier conversion, SPAKE M and N constants, and associated hash function.

12.2.1. Registration Template

ID Number: This is a value that uniquely identifies this entry. It is a signed integer in range -2147483648 to 2147483647, inclusive. Positive values must be assigned only for algorithms specified in accordance with these rules for use with Kerberos and related protocols. Negative values should be used for private

and experimental use only. Zero is reserved and must not be assigned. Values should be assigned in increasing order.

Name: Brief, unique, human readable name for this entry.

Specification: Reference to the definition of the group parameters and operations.

Serialization: Reference to the definition of the method used to serialize and deserialize group elements.

Multiplier Length: The length of the input octet string to multiplication operations.

Multiplier Conversion: Reference to the definition of the method used to convert an octet string to a multiplier scalar.

SPAKE M Constant: The serialized value of the SPAKE M constant in hexadecimal notation.

SPAKE N Constant: The serialized value of the SPAKE N constant in hexadecimal notation.

Hash Function: The group's associated hash function.

12.2.2. Initial Registry Contents

ID Number: 1

Name: edwards25519

Specification: Section 4.1 of [[RFC7748](#)] (edwards25519)

Serialization: Section 3.1 of [[RFC8032](#)]

Multiplier Length: 32

Multiplier Conversion: Section 3.1 of [[RFC8032](#)]

SPAKE M Constant:

d048032c6ea0b6d697ddc2e86bda85a33adac920f1bf18e1b0c6d166a5cecdaf

SPAKE N Constant:

}

END

```

Appendix B. SPAKE M and N Value Selection

The M and N values for the initial contents of the SPAKE group registry were generated using the following Python snippet, which assumes an elliptic curve implementation following the interface of `Edwards25519Point.stdbase()` and `Edwards448Point.stdbase()` in Appendix A of [\[RFC8032\]](#):

```
def iterhash(seed, n):
    h = seed
    for i in range(n):
        h = hashlib.sha256(h).digest()
    return h

def bighash(seed, start, sz):
    n = -(-sz // 32)
    hashes = [iterhash(seed, i) for i in range(start, start + n)]
    return b''.join(hashes)[:sz]

def canon_pointstr(ecname, s):
    if ecname == 'edwards25519':
        return s
    elif ecname == 'edwards448':
        return s[:-1] + bytes([s[-1] & 0x80])
    else:
        return bytes([(s[0] & 1) | 2]) + s[1:]

def gen_point(seed, ecname, ec):
    for i in range(1, 1000):
        hval = bighash(seed, i, len(ec.encode()))
        pointstr = canon_pointstr(ecname, hval)
        try:
            p = ec.decode(pointstr)
            if p != ec.zero_elem() and p * p.l() == ec.zero_elem():
                return pointstr, i
        except Exception:
            pass
```

The seed initial seed strings are:

*For group 1 M: edwards25519 point generation seed (M)

*For group 1 N: edwards25519 point generation seed (N)

*For group 2 M: 1.2.840.10045.3.1.7 point generation seed (M)

*For group 2 N: 1.2.840.10045.3.1.7 point generation seed (N)

*For group 3 M: 1.3.132.0.34 point generation seed (M)

*For group 3 N: 1.3.132.0.34 point generation seed (N)

*For group 4 M: 1.3.132.0.35 point generation seed (M)

*For group 4 N: 1.3.132.0.35 point generation seed (N)

Appendix C. Test Vectors

For the following text vectors:

*The key is the string-to-key of "password" with the salt "ATHENA.MIT.EDUraeburn" for the designated initial reply key encryption type.

*x and y were chosen randomly within the order of the designated group, then multiplied by the cofactor..

*The SPAKESupport message contains only the designated group's number.

*The SPAKEChallenge message offers only the SF-NONE second factor type.

*The KDC-REQ-BODY message contains no KDC options, the client principal name "raeburn@ATHENA.MIT.EDU", the server principal name "krbtgt/ATHENA.MIT.EDU", the realm "ATHENA.MIT.EDU", the till field "19700101000000Z", the nonce zero, and an etype list containing only the designated encryption type.

There are currently no encryption types with a seed size large enough to require multiple hash blocks during key derivation with any of the assigned hash functions. To exercise this possibility, the following test vector illustrates what keys would be derived if there were a copy of the edwards25519 group with group number -1 and associated hash function SHA-1:

```
AES256 edwards25519 SHA-1 group number -1
key: 01b897121d933ab44b47eb5494db15e50eb74530dbdae9b634d65020ff5d88c1
