Using Pre-Shared Key (PSK) in the Cryptographic Message Syntax (CMS)
<draft-ietf-lamps-cms-mix-with-psk-06.txt>

Abstract

   The invention of a large-scale quantum computer would pose a serious
   challenge for the cryptographic algorithms that are widely deployed
   today. The Cryptographic Message Syntax (CMS) supports key transport
   and key agreement algorithms that could be broken by the invention of
   such a quantum computer. By storing communications that are
   protected with the CMS today, someone could decrypt them in the
   future when a large-scale quantum computer becomes available. Once
   quantum-secure key management algorithms are available, the CMS will
   be extended to support the new algorithms, if the existing syntax
   does not accommodate them. In the near-term, this document describes
   a mechanism to protect today's communication from the future
   invention of a large-scale quantum computer by mixing the output of
   key transport and key agreement algorithms with a pre-shared key.

Status of this Memo

   This Internet-Draft is submitted in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF). Note that other groups may also distribute
   working documents as Internet-Drafts. The list of current Internet-
   Drafts is at http://datatracker.ietf.org/drafts/current/.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

[1](#). Introduction

The invention of a large-scale quantum computer would pose a serious
challenge for the cryptographic algorithms that are widely deployed
today [[S1994](#)]. It is an open question whether or not it is feasible
to build a large-scale quantum computer, and if so, when that might
happen [[NAS2019](#)]. However, if such a quantum computer is invented,
many of the cryptographic algorithms and the security protocols that
use them would become vulnerable.

The Cryptographic Message Syntax (CMS) [RFC5652][RFC5083] supports
key transport and key agreement algorithms that could be broken by
the invention of a large-scale quantum computer [C2PQ]. These
algorithms include RSA [RFC8017], Diffie-Hellman [RFC2631], and
Elliptic Curve Diffie-Hellman [RFC5753]. As a result, an adversary
that stores CMS-protected communications today, could decrypt those
communications in the future when a large-scale quantum computer
becomes available.

Once quantum-secure key management algorithms are available, the CMS
will be extended to support them, if the existing syntax does not
already accommodate the new algorithms.

In the near-term, this document describes a mechanism to protect
today's communication from the future invention of a large-scale
quantum computer by mixing the output of existing key transport and
key agreement algorithms with a pre-shared key (PSK). Secure
communication can be achieved today by mixing a strong PSK with the
output of an existing key transport algorithm, like RSA [RFC8017], or
an existing key agreement algorithm, like Diffie-Hellman [RFC2631] or
Elliptic Curve Diffie-Hellman [RFC5753]. A security solution that is
believed to be quantum resistant can be achieved by using a PSK with
sufficient entropy along with a quantum resistant key derivation
function (KDF), like HKDF [RFC5869], and a quantum resistant
encryption algorithm, like 256-bit AES [AES]. In this way, today's
CMS-protected communication can be resistant to an attacker with a
large-scale quantum computer.

In addition, there may be other reasons for including a strong PSK
besides protection against the future invention of a large-scale
quantum computer. For example, there is always the possibility of a
cryptoanalytic breakthrough on one or more of the classic public-key
algorithm, and there are longstanding concerns about undisclosed
trapdoors in Diffie-Hellman parameters [FGHT2016]. Inclusion of a
strong PSK as part of the overall key management offer additional
protection against these concerns.

Note that the CMS also supports key management techniques based on
symmetric key-encryption keys and passwords, but they are not
discussed in this document because they are already quantum
resistant. The symmetric key-encryption key technique is quantum
resistant when used with an adequate key size. The password
technique is quantum resistant when used with a quantum-resistant key
derivation function and a sufficiently large password.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and
"OPTIONAL" in this document are to be interpreted as described in
BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all
capitals, as shown here.

1.2. ASN.1

CMS values are generated using ASN.1 [X680], which uses the Basic
Encoding Rules (BER) and the Distinguished Encoding Rules (DER)
[X690].

1.3. Version Numbers

The major data structures include a version number as the first item
in the data structure. The version number is intended to avoid ASN.1
decode errors. Some implementations do not check the version number
prior to attempting a decode, and then if a decode error occurs, the
version number is checked as part of the error handling routine.
This is a reasonable approach; it places error processing outside of
the fast path. This approach is also forgiving when an incorrect
version number is used by the sender.

Whenever the structure is updated, a higher version number will be
assigned. However, to ensure maximum interoperability, the higher
version number is only used when the new syntax feature is employed.
That is, the lowest version number that supports the generated syntax
is used.

2. Overview

The CMS enveloped-data content type [RFC5652] and the CMS
authenticated-enveloped-data content type [RFC5083] support both key
transport and key agreement public-key algorithms to establish the
key used to encrypt the content. No restrictions are imposed on the
key transport or key agreement public-key algorithms, which means
that any key transport or key agreement algorithm can be used,
including algorithms that are specified in the future. In both
cases, the sender randomly generates the content-encryption key, and
then all recipients obtain that key. All recipients use the sender-
generated symmetric content-encryption key for decryption.

This specification defines two quantum-resistant ways to establish a
symmetric key-encryption key, which is used to encrypt the sender-
generated content-encryption key. In both cases, the PSK is used as
one of the inputs to a key-derivation function to create a quantum-

resistant key-encryption key. The PSK MUST be distributed to the
sender and all of the recipients by some out-of-band means that does
not make it vulnerable to the future invention of a large-scale
quantum computer, and an identifier MUST be assigned to the PSK.

The content-encryption key or content-authenticated-encryption key is
quantum-resistant, and the sender establishes it using these steps:

   When using a key transport algorithm:

   1. The content-encryption key or the content-authenticated-
      encryption key, called CEK, is generated at random.

   2. The key-derivation key, called KDK, is generated at random.

   3. For each recipient, the KDK is encrypted in the recipient's
      public key, then the key derivation function (KDF) is used to
      mix the pre-shared key (PSK) and the KDK to produce the key-
      encryption key, called KEK.

   4. The KEK is used to encrypt the CEK.

   When using a key agreement algorithm:

   1. The content-encryption key or the content-authenticated-
      encryption key, called CEK, is generated at random.

   2. For each recipient, a pairwise key-encryption key, called KEK1,
      is established using the recipient's public key and the
      sender's private key. Note that KEK1 will be used as a key-
      derivation key.

   3. For each recipient, the key derivation function (KDF) is used
      to mix the pre-shared key (PSK) and the pairwise KEK1, and the
      result is called KEK2.

   4. For each recipient, the pairwise KEK2 is used to encrypt the
      CEK.

As specified in Section 6.2.5 of [RFC5652], recipient information for
additional key management techniques are represented in the
OtherRecipientInfo type. Two key management techniques are specified
in this document, and they are each identified by a unique ASN.1
object identifier.

The first key management technique, called keyTransPSK, see
Section 3, uses a key transport algorithm to transfer the key-
derivation key from the sender to the recipient, and then the key-

   derivation key is mixed with the PSK using a KDF. The output of the
   KDF is the key-encryption key, which is used for the encryption of
   the content-encryption key or content-authenticated-encryption key.

   The second key management technique, called keyAgreePSK, see
   Section 4, uses a key agreement algorithm to establish a pairwise
   key-encryption key, which is then mixed with the PSK using a KDF to
   produce a second pairwise key-encryption key, which is then used to
   encrypt the content-encryption key or content-authenticated-
   encryption key.

3. keyTransPSK

   Per-recipient information using keyTransPSK is represented in the
   KeyTransPSKRecipientInfo type, which is indicated by the id-ori-
   keyTransPSK object identifier. Each instance of
   KeyTransPSKRecipientInfo establishes the content-encryption key or
   content-authenticated-encryption key for one or more recipients that
   have access to the same PSK.

   The id-ori-keyTransPSK object identifier is:

      id-ori OBJECT IDENTIFIER ::= { iso(1) member-body(2) us(840)
        rsadsi(113549) pkcs(1) pkcs-9(9) smime(16) TBD1 }

      id-ori-keyTransPSK OBJECT IDENTIFIER ::= { id-ori 1 }

   The KeyTransPSKRecipientInfo type is:

      KeyTransPSKRecipientInfo ::= SEQUENCE {
        version CMSVersion, -- always set to 0
        pskid PreSharedKeyIdentifier,
        kdfAlgorithm KeyDerivationAlgorithmIdentifier,
        keyEncryptionAlgorithm KeyEncryptionAlgorithmIdentifier,
        ktris KeyTransRecipientInfos,
        encryptedKey EncryptedKey }

      PreSharedKeyIdentifier ::= OCTET STRING

      KeyTransRecipientInfos ::= SEQUENCE OF KeyTransRecipientInfo

   The fields of the KeyTransPSKRecipientInfo type have the following
   meanings:

      version is the syntax version number. The version MUST be 0. The
      CMSVersion type is described in Section 10.2.5 of [RFC5652].

      pskid is the identifier of the PSK used by the sender. The
      identifier is an OCTET STRING, and it need not be human readable.

      kdfAlgorithm identifies the key-derivation algorithm, and any
      associated parameters, used by the sender to mix the key-
      derivation key and the PSK to generate the key-encryption key.
      The KeyDerivationAlgorithmIdentifier is described in Section
      10.1.6 of [RFC5652].

      keyEncryptionAlgorithm identifies a key-encryption algorithm used
      to encrypt the content-encryption key. The
      KeyEncryptionAlgorithmIdentifier is described in Section 10.1.3 of
      [RFC5652].

      ktris contains one KeyTransRecipientInfo type for each recipient;
      it uses a key transport algorithm to establish the key-derivation
      key. KeyTransRecipientInfo is described in Section 6.2.1 of
      [RFC5652].

      encryptedKey is the result of encrypting the content-encryption
      key or the content-authenticated-encryption key with the key-
      encryption key. EncryptedKey is an OCTET STRING.

4. keyAgreePSK

   Per-recipient information using keyAgreePSK is represented in the
   KeyAgreePSKRecipientInfo type, which is indicated by the id-ori-
   keyAgreePSK object identifier. Each instance of
   KeyAgreePSKRecipientInfo establishes the content-encryption key or
   content-authenticated-encryption key for one or more recipients that
   have access to the same PSK.

   The id-ori-keyAgreePSK object identifier is:

      id-ori-keyAgreePSK OBJECT IDENTIFIER ::= { id-ori 2 }

   The KeyAgreePSKRecipientInfo type is:

      KeyAgreePSKRecipientInfo ::= SEQUENCE {
        version CMSVersion, -- always set to 0
        pskid PreSharedKeyIdentifier,
        originator [0] EXPLICIT OriginatorIdentifierOrKey,
        ukm [1] EXPLICIT UserKeyingMaterial OPTIONAL,
        kdfAlgorithm KeyDerivationAlgorithmIdentifier,
        keyEncryptionAlgorithm KeyEncryptionAlgorithmIdentifier,
        recipientEncryptedKeys RecipientEncryptedKeys }

The fields of the KeyAgreePSKRecipientInfo type have the following
meanings:

   version is the syntax version number. The version MUST be 0. The
   CMSVersion type is described in Section 10.2.5 of [RFC5652].

   pskid is the identifier of the PSK used by the sender. The
   identifier is an OCTET STRING, and it need not be human readable.

   originator is a CHOICE with three alternatives specifying the
   sender's key agreement public key. Implementations MUST support
   all three alternatives for specifying the sender's public key.
   The sender uses their own private key and the recipient's public
   key to generate a pairwise key-encryption key. A key derivation
   function (KDF) is used to mix the PSK and the pairwise key-
   encryption key to produce a second key-encryption key. The
   OriginatorIdentifierOrKey type is described in Section 6.2.2 of
   [RFC5652].

   ukm is optional. With some key agreement algorithms, the sender
   provides a User Keying Material (UKM) to ensure that a different
   key is generated each time the same two parties generate a
   pairwise key. Implementations MUST accept a
   KeyAgreePSKRecipientInfo SEQUENCE that includes a ukm field.
   Implementations that do not support key agreement algorithms that
   make use of UKMs MUST gracefully handle the presence of UKMs. The
   UserKeyingMaterial type is described in Section 10.2.6 of
   [RFC5652].

   kdfAlgorithm identifies the key-derivation algorithm, and any
   associated parameters, used by the sender to mix the pairwise key-
   encryption key and the PSK to produce a second key-encryption key
   of the same length as the first one. The
   KeyDerivationAlgorithmIdentifier is described in Section 10.1.6 of
   [RFC5652].

   keyEncryptionAlgorithm identifies a key-encryption algorithm used
   to encrypt the content-encryption key or the content-
   authenticated-encryption key. The
   KeyEncryptionAlgorithmIdentifier type is described in Section
   10.1.3 of [RFC5652].

   recipientEncryptedKeys includes a recipient identifier and
   encrypted key for one or more recipients. The
   KeyAgreeRecipientIdentifier is a CHOICE with two alternatives
   specifying the recipient's certificate, and thereby the
   recipient's public key, that was used by the sender to generate a
   pairwise key-encryption key. The encryptedKey is the result of

   encrypting the content-encryption key or the content-
   authenticated-encryption key with the second pairwise key-
   encryption key. EncryptedKey is an OCTET STRING. The
   RecipientEncryptedKeys type is defined in Section 6.2.2 of
    [RFC5652].

5. Key Derivation

   Many key derivation functions (KDFs) internally employ a one-way hash
   function. When this is the case, the hash function that is used is
   identified by the KeyDerivationAlgorithmIdentifier. HKDF [RFC5869]
   is one example of a KDF that makes use of a hash function.

   A KDF has several input values. This section describes the
   conventions for using the KDF to compute the key-encryption key for
   KeyTransPSKRecipientInfo and KeyAgreePSKRecipientInfo. For
   simplicity, the terminology used in the HKDF [RFC5869] specification
   is used here.

   The KDF inputs are:

      IKM is the input keying material; it is the symmetric secret input
      to the KDF. For KeyTransPSKRecipientInfo, it is the key-
      derivation key. For KeyAgreePSKRecipientInfo, it is the pairwise
      key-encryption key produced by the key agreement algorithm.

      salt is an optional non-secret random value. The salt is not
      used.

      L is the length of output keying material in octets; the value
      depends on the key-encryption algorithm that will be used. The
      algorithm is identified by the KeyEncryptionAlgorithmIdentifier.
      In addition, the OBJECT IDENTIFIER portion of the
      KeyEncryptionAlgorithmIdentifier is included in the next input
      value, called info.

      info is optional context and application specific information.
      The DER-encoding of CMSORIforPSKOtherInfo is used as the info
      value, and the PSK is included in this structure. Note that
      EXPLICIT tagging is used in the ASN.1 module that defines this
      structure. For KeyTransPSKRecipientInfo, the ENUMERATED value of
      5 is used. For KeyAgreePSKRecipientInfo, the ENUMERATED value of
      10 is used. CMSORIforPSKOtherInfo is defined by the following

ASN.1 structure:

```
CMSORIforPSKOtherInfo ::= SEQUENCE {
  psk                    OCTET STRING,
  keyMgmtAlgType         ENUMERATED {
    keyTrans             (5),
    keyAgree             (10) },
  keyEncryptionAlgorithm KeyEncryptionAlgorithmIdentifier,
  pskLength              INTEGER (1..MAX),
  kdkLength              INTEGER (1..MAX) }
```

The fields of type CMSORIforPSKOtherInfo have the following meanings:

psk is an OCTET STRING; it contains the PSK.

keyMgmtAlgType is either set to 5 or 10. For
KeyTransPSKRecipientInfo, the ENUMERATED value of 5 is used. For
KeyAgreePSKRecipientInfo, the ENUMERATED value of 10 is used.

keyEncryptionAlgorithm is the KeyEncryptionAlgorithmIdentifier,
which identifies the algorithm and provides algorithm parameters,
if any.

pskLength is a positive integer; it contains the length of the PSK
in octets.

kdkLength is a positive integer; it contains the length of the
key-derivation key in octets. For KeyTransPSKRecipientInfo, the
key-derivation key is generated by the sender. For
KeyAgreePSKRecipientInfo, the key-derivation key is the pairwise
key-encryption key produced by the key agreement algorithm.

The KDF output is:

OKM is the output keying material, which is exactly L octets. The
OKM is the key-encryption key that is used to encrypt the content-
encryption key or the content-authenticated-encryption key.

6. ASN.1 Module

This section contains the ASN.1 module for the two key management
techniques defined in this document. This module imports types from
other ASN.1 modules that are defined in [RFC5911] and [RFC5912].

7. **Security Considerations**

   Implementations must protect the pre-shared key (PSK), key transport
   private key, the agreement private key, the key-derivation key, and
   the key-encryption key. Compromise of the PSK will make the
   encrypted content vulnerable to the future invention of a large-scale
   quantum computer. Compromise of the PSK and either the key transport
   private key or the agreement private key may result in the disclosure
   of all contents protected with that combination of keying material.
   Compromise of the PSK and the key-derivation key may result in
   disclosure of all contents protected with that combination of keying
   material. Compromise of the key-encryption key may result in the
   disclosure of all content-encryption keys or content-authenticated-
   encryption keys that were protected with that keying material, which
   in turn may result in the disclosure of the content.

   A large-scale quantum computer will essentially negate the security
   provided by the key transport algorithm or the key agreement
   algorithm, which means that the attacker with a large-scale quantum
   computer can discover the key-derivation key. In addition a large-
   scale quantum computer effectively cuts the security provided by a
   symmetric key algorithm in half. Therefore, the PSK needs at least
   256 bits of entropy to provide 128 bits of security. To match that
   same level of security, the key derivation function needs to be
   quantum-resistant and produce a key-encryption key that is at least
   256 bits in length. Similarly, the content-encryption key or
   content-authenticated-encryption key needs to be at least 256 bits in
   length.

   When using a PSK with a key transport or a key agreement algorithm, a
   key-encryption key is produced to encrypt the content-encryption key
   or content-authenticated-encryption key. If the key-encryption
   algorithm is different than the algorithm used to protect the
   content, then the effective security is determined by the weaker of
   the two algorithms. If, for example, content is encrypted with
   256-bit AES, and the key is wrapped with 128-bit AES, then at most
   128 bits of protection is provided. Implementers must ensure that
   the key-encryption algorithm is as strong or stronger than the
   content-encryption algorithm or content-authenticated-encryption
   algorithm.

   Implementers should not mix quantum-resistant key management
   algorithms with their non-quantum-resistant counterparts. For
   example, the same content should not be protected with
   KeyTransRecipientInfo and KeyTransPSKRecipientInfo. Likewise, the
   same content should not be protected with KeyAgreeRecipientInfo and
   KeyAgreePSKRecipientInfo. Doing so would make the content vulnerable
   to the future invention of a large-scale quantum computer.

Implementers should not send the same content in different messages,
one using a quantum-resistant key management algorithm and the other
using a non-quantum-resistant key management algorithm, even if the
content-encryption key is generated independently. Doing so may
allow an eavesdropper to correlate the messages, making the content
vulnerable to the future invention of a large-scale quantum computer.

This specification does not require that PSK is known only by the
sender and recipients. The PSK may be known to a group. Since
confidentiality depends on the key transport or key agreement
algorithm, knowledge of the PSK by other parties does not enable
eavesdropping. However, group members can record the traffic of
other members, and then decrypt it if they ever gain access to a
large-scale quantum computer. Also, when many parties know the PSK,
there are many opportunities for theft of the PSK by an attacker.
Once an attacker has the PSK, they can decrypt stored traffic if they
ever gain access to a large-scale quantum computer in the same manner
as a legitimate group member.

Sound cryptographic key hygiene is to use a key for one and only one
purpose. Use of the recipient's public key for both the traditional
CMS and the PSK-mixing variation specified in this document would be
a violation of this principle; however, there is no known way for an
attacker to take advantage of this situation. That said, an
application should enforce separation whenever possible. For
example, a purpose identifier for use in the X.509 extended key usage
certificate extension [RFC5280] could be identified in the future to
indicate that a public key should only be used in conjunction with a
PSK, or only without.

Implementations must randomly generate key-derivation keys as well as
the content-encryption keys or content-authenticated-encryption keys.
Also, the generation of public/private key pairs for the key
transport and key agreement algorithms rely on a random numbers. The
use of inadequate pseudo-random number generators (PRNGs) to generate
cryptographic keys can result in little or no security. An attacker
may find it much easier to reproduce the PRNG environment that
produced the keys, searching the resulting small set of
possibilities, rather than brute force searching the whole key space.
The generation of quality random numbers is difficult. [RFC4086]
offers important guidance in this area.

Implementers should be aware that cryptographic algorithms become
weaker with time. As new cryptoanalysis techniques are developed and
computing performance improves, the work factor to break a particular
cryptographic algorithm will be reduced. Therefore, cryptographic
algorithm implementations should be modular, allowing new algorithms
to be readily inserted. That is, implementers should be prepared for

the set of supported algorithms to change over time.

The security properties provided by the mechanisms specified in this
document can be validated using formal methods. A ProVerif proof in
[H2019] shows that an attacker with a large-scale quantum computer
that is capable of breaking the Diffie-Hellman key agreement
algorithm cannot disrupt the delivery of the content-encryption key
to the recipient and the attacker cannot learn the content-encryption
key from the protocol exchange.

8. Privacy Considerations

An observer can see which parties are using each PSK simply by
watching the PSK key identifiers. However, the addition of these key
identifiers is not really making privacy worse. When key transport
is used, the RecipientIdentifier is always present, and it clearly
identifies each recipient to an observer. When key agreement is
used, either the IssuerAndSerialNumber or the RecipientKeyIdentifier
is always present, and these clearly identify each recipient.

9. IANA Considerations

One object identifier for the ASN.1 module in Section 6 was assigned
in the SMI Security for S/MIME Module Identifiers
(1.2.840.113549.1.9.16.0) [IANA-MOD] registry:

```
   id-mod-cms-ori-psk-2019 OBJECT IDENTIFIER ::= {
      iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1)
      pkcs-9(9) smime(16) mod(0) TBD0 }
```

One new registry was created for Other Recipient Info Identifiers
within the SMI Security for S/MIME Mail Security
(1.2.840.113549.1.9.16) [IANA-SMIME] registry:

```
   id-ori OBJECT IDENTIFIER ::= { iso(1) member-body(2) us(840)
     rsadsi(113549) pkcs(1) pkcs-9(9) smime(16) TBD1 }
```

Two assignments were made in the new SMI Security for Other Recipient
Info Identifiers (1.2.840.113549.1.9.16.TBD1) [IANA-ORI] registry
with references to this document:

```
   id-ori-keyTransPSK OBJECT IDENTIFIER ::= {
      iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1)
      pkcs-9(9) smime(16) id-ori(TBD1) 1 }

   id-ori-keyAgreePSK OBJECT IDENTIFIER ::= {
      iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1)
      pkcs-9(9) smime(16) id-ori(TBD1) 2 }
```

Appendix A: Key Transport with PSK Example

   This example shows the establishment of an AES-256 content-encryption
   key using:
      - a pre-shared key of 256 bits;
      - key transport using RSA PKCS#1 v1.5 with a 3072-bit key;
      - key derivation using HKDF with SHA-384; and
      - key wrap using AES-256-KEYWRAP.

   In real-world use, the originator would encrypt the key-derivation
   key in their own RSA public key as well as the recipient's public
   key. This is omitted in an attempt to simplify the example.

. **Originator Processing Example**

   The pre-shared key known to Alice and Bob:
      c244cdd11a0d1f39d9b61282770244fb0f6befb91ab7f96cb05213365cf95b15

   The identifier assigned to the pre-shared key is:
      ptf-kmc:13614122112

   Alice obtains Bob's public key:
      -----BEGIN PUBLIC KEY-----
      MIIBojANBgkqhkiG9w0BAQEFAAOCAY8AMIIBigKCAYEA3ocW14cxncPJ47fnEjBZ
      AyfC2lqapL3ET4jvV6C7gGeVrRQxWPDwl+cFYBBR2ej3j3/0ecDmu+XuVi2+s5JH

   Alice produces a 256-bit key-encryption key with HKDF using SHA-384;
   the secret value is the key-derivation key; the 'info' is the DER-
   encoded CMSORIforPSKOtherInfo structure with the following values:
```
     0   56: SEQUENCE {
     2   32:   OCTET STRING
           :      C2 44 CD D1 1A 0D 1F 39 D9 B6 12 82 77 02 44 FB
           :      0F 6B EF B9 1A B7 F9 6C B0 52 13 36 5C F9 5B 15
    36    1:   ENUMERATED 5
    39   11:   SEQUENCE {
    41    9:     OBJECT IDENTIFIER aes256-wrap
           :        { 2 16 840 1 101 3 4 1 45 }
           :     }
    52    1:   INTEGER 32
    55    1:   INTEGER 32
           :   }
```

   The DER encoding of CMSORIforPSKOtherInfo produces 58 octets:
      30380420c244cdd11a0d1f39d9b61282770244fb0f6befb91ab7f96cb0521336
      5cf95b150a0105300b0609608648016503040012d020120020120

   The HKDF output is 256 bits:
      a14d87451dfd11d83cd54ffe2bd38c49a2adfed3ac49f1d3e62bbdc64ae43b32

   Alice uses AES-KEY-WRAP to encrypt the 256-bit content-encryption
   key with the key-encryption key:
      ae4ea1d99e78fcdcea12d9f10d991ac71502939ee0c30ebdcc97dd1fc5ba3566
      c83d0dd5d1b4faa5

   Alice encrypts the content using AES-256-GCM with the content-
   encryption key. The 12-octet nonce used is:
      cafebabefacedbaddecaf888

   The content plaintext is:
      48656c6c6f2c20776f726c6421

   The resulting ciphertext is:
      9af2d16f21547fcefed9b3ef2d

   The resulting 12-octet authentication tag is:
      a0e5925cc184e0172463c44c

A.2. ContentInfo and AuthEnvelopedData

   Alice encodes the AuthEnvelopedData and the ContentInfo, and
   sends the result to Bob. The resulting structure is:

```
   0  650: SEQUENCE {
   4   11:   OBJECT IDENTIFIER authEnvelopedData
        :    { 1 2 840 113549 1 9 16 1 23 }
  17  633:   [0] {
  21  629:    SEQUENCE {
  25    1:     INTEGER 0
  28  551:     SET {
  32  547:      [4] {
  36   11:        OBJECT IDENTIFIER ** Placeholder **
        :          { 1 2 840 113549 1 9 16 TBD 1 }
  49  530:        SEQUENCE {
  53    1:         INTEGER 0
  56   19:         OCTET STRING 'ptf-kmc:13614122112'
  77   13:         SEQUENCE {
  79   11:          OBJECT IDENTIFIER ** Placeholder **
        :            { 1 2 840 113549 1 9 16 3 TBD }
        :            }
  92   11:         SEQUENCE {
  94    9:          OBJECT IDENTIFIER aes256-wrap
        :            { 2 16 840 1 101 3 4 1 45 }
        :            }
 105  432:         SEQUENCE {
 109  428:          SEQUENCE {
 113    1:           INTEGER 2
 116   20:           [0]

      -----END RSA PRIVATE KEY-----

   Bob decrypts the key-derivation key with his RSA private key:
      df85af9e3cebffde6e9b9d24263db31114d0a8e33a0d50e05eb64578ccde81eb

   Bob produces a 256-bit key-encryption key with HKDF using SHA-384;
   the secret value is the key-derivation key; the 'info' is the DER-
   encoded CMSORIforPSKOtherInfo structure with the same values as
   shown in A.1. The HKDF output is 256 bits:
      a14d87451dfd11d83cd54ffe2bd38c49a2adfed3ac49f1d3e62bbdc64ae43b32

   Bob uses AES-KEY-WRAP to decrypt the content-encryption key
   with the key-encryption key; the content-encryption key is:
      c8adc30f4a3e20ac420caa76a68f5787c02ab42afea20d19672fd963a5338e83

   Bob decrypts the content using AES-256-GCM with the content-
   encryption key, and checks the received authentication tag. The
   12-octet nonce used is:
      cafebabefacedbaddecaf888

   The 12-octet authentication tag is:
      a0e5925cc184e0172463c44c

   The received ciphertext content is:
      9af2d16f21547fcefed9b3ef2d

   The resulting plaintext content is:
      48656c6c6f2c20776f726c6421

Appendix B: Key Agreement with PSK Example

   This example shows the establishment of an AES-256 content-encryption
   key using:
      - a pre-shared key of 256 bits;
      - key agreement using ECDH on curve P-384 and X9.63 KDF
        with SHA-384;
      - key derivation using HKDF with SHA-384; and
      - key wrap using AES-256-KEYWRAP.

   In real-world use, the originator would treat themselves as an
   additional recipient by performing key agreement with their own
   static public key and the ephemeral private key generated for this
   message. This is omitted in an attempt to simplify the example.

B.1. Originator Processing Example

   The pre-shared key known to Alice and Bob:
      4aa53cbf500850dd583a5d9821605c6fa228fb5917f87c1c078660214e2d83e4

   The identifier assigned to the pre-shared key is:
      ptf-kmc:216840110121

   Alice randomly generates a content-encryption key:
      937b1219a64d57ad81c05cc86075e86017848c824d4e85800c731c5b7b091033

   Alice obtains Bob's static ECDH public key:
      -----BEGIN PUBLIC KEY-----
      MHYwEAYHKoZIzj0CAQYFK4EEACIDYgAEScGPBO9nmUwGrgbGEoFY9HR/bCo0WyeY
      /dePQVrwZmwN2yMJmO2d1kWCvLTz8U7atinxyIRe9CV54yau1KWU/wbkhPDnzuSM
      YkcpxMGo32z3JetEloW5aFOja13vv/W5
      -----END PUBLIC KEY-----

   It has a key identifier of:
      e8218b98b8b7d86b5e9ebdc8aeb8c4ecdc05c529

   Alice generates an ephemeral ECDH key pair on the same curve:
      -----BEGIN EC PRIVATE KEY-----
      MIGkAgEBBDCMiWLG44ik+L8cYVvJrQdLcFA+PwlgRF+Wt1Ab25qUh8OB7OePWjxp
      /b8P6IOuI6GgBwYFK4EEACKhZANiAAQ5G0EmJk/2ks8sXY1kzbuG3Uu3ttWwQRXA
      LFDJICjvYfr+yTpOQVkchm88FAh9MEkw4NKctokKNgpsqXyrT3DtOg76oIYENpPb
      GE5lJdjPx9sBsZQdABwlsU0Zb7P/7i8=
      -----END EC PRIVATE KEY-----

   Alice computes a shared secret, called Z, using the Bob's static
   ECDH public key and her ephemeral ECDH private key; Z is:
      3f015ed0ff4b99523a95157bbe77e9cc0ee52fcffeb7e41eac79d1c11b6cc556
      19cf8807e6d800c2de40240fe0e26adc

   Alice computes the pairwise key-encryption key, called KEK1, from Z
   using the X9.63 KDF with the ECC-CMS-SharedInfo structure with the
   following values:
        0   21: SEQUENCE {
        2   11:   SEQUENCE {
        4   9:   OBJECT IDENTIFIER aes256-wrap
         :   { 2 16 840 1 101 3 4 1 45 }
         :   }
       15   6:   [2] {
       17   4:   OCTET STRING 00 00 00 20
         :   }
         :   }

   The DER encoding of ECC-CMS-SharedInfo produces 23 octets:
      3015300b060960864801650304012da206040400000020

   The X9.63 KDF output is the 256-bit KEK1:
      27dc25ddb0b425f7a968ceada80a8f73c6ccaab115baafcce4a22a45d6b8f3da

Alice produces the 256-bit KEK2 with HKDF using SHA-384; the secret
value is KEK1; the 'info' is the DER-encoded CMSORIforPSKOtherInfo
structure with the following values:
```
    0   56: SEQUENCE {
    2   32:   OCTET STRING
          :      4A A5 3C BF 50 08 50 DD 58 3A 5D 98 21 60 5C 6F
          :      A2 28 FB 59 17 F8 7C 1C 07 86 60 21 4E 2D 83 E4
   36    1:   ENUMERATED 10
   39   11:   SEQUENCE {
   41    9:     OBJECT IDENTIFIER aes256-wrap
          :        { 2 16 840 1 101 3 4 1 45 }
          :        }
   52    1:   INTEGER 32
   55    1:   INTEGER 32
          :   }
```

The DER encoding of CMSORIforPSKOtherInfo produces 58 octets:
```
   303804204aa53cbf500850dd583a5d9821605c6fa228fb5917f87c1c07866021
   4e2d83e40a010a300b060960864801650304012d020120020120
```

The HKDF output is the 256-bit KEK2:
```
   7de693ee30ae22b5f8f6cd026c2164103f4e1430f1ab135dc1fb98954f9830bb
```

Alice uses AES-KEY-WRAP to encrypt the content-encryption key
with the KEK2; the wrapped key is:
```
   229fe0b45e40003e7d8244ec1b7e7ffb2c8dca16c36f5737222553a71263a92b
   de08866a602d63f4
```

Alice encrypts the content using AES-256-GCM with the content-
encryption key. The 12-octet nonce used is:
```
   dbaddecaf888cafebabeface
```

The plaintext is:
```
   48656c6c6f2c20776f726c6421
```

The resulting ciphertext is:
```
   fc6d6f823e3ed2d209d0c6ffcf
```

The resulting 12-octet authentication tag is:
```
   550260c42e5b29719426c1ff
```

B.2. **ContentInfo and AuthEnvelopedData**

   Alice encodes the AuthEnvelopedData and the ContentInfo, and
   sends the result to Bob. The resulting structure is:

```
     0  327: SEQUENCE {
     4   11:  OBJECT IDENTIFIER authEnvelopedData
           :  { 1 2 840 113549 1 9 16 1 23 }
    17  310:  [0] {
    21  306:   SEQUENCE {
    25    1:    INTEGER 0
    28  229:    SET {
    31  226:     [4] {
    34   11:       OBJECT IDENTIFIER ** Placeholder **
           :          { 1 2 840 113549 1 9 16 TBD 2 }
    47  210:        SEQUENCE {
    50    1:         INTEGER 0
    53   20:         OCTET STRING 'ptf-kmc:216840110121'
    75   85:         [0] {
    77   83:          [1] {
    79   19:            SEQUENCE {
    81    6:             OBJECT IDENTIFIER
           :              dhSinglePass-stdDH-sha256kdf-scheme
           :              { 1 3 132 1 11 1 }
    89    9:             OBJECT IDENTIFIER aes256-wrap
           :              { 2 16 840 1 101 3 4 1 45 }
           :             }
   100   60:            BIT STRING, encapsulates {
   103   57:             OCTET STRING
           :             1B 41 26 26 4F F6 92 CF 2C 5D 8D 64 CD BB 86 DD
           :             4B B7 B6 D5 B0 41 15 C0 2C 50 C9 20 28 EF 61 FA
           :             FE C9 3A 4E 41 59 1C 86 6F 3C 14 08 7D 30 49 30
           :             E0 D2 9C B6 89 0A 36 0A 6C
           :             }
           :            }
           :          }
   162   13:         SEQUENCE {
   164   11:          OBJECT IDENTIFIER ** Placeholder **
           :           { 1 2 840 113549 1 9 16 3 TBD }
           :          }
   177   11:         SEQUENCE {

           :    }
           :   }
```

B.3. Recipient Processing Example

Bob obtains Alice's ephemeral ECDH public key from the message:

```
    -----BEGIN PUBLIC KEY-----
    MHYwEAYHKoZIzj0CAQYFK4EEACIDYgAEORtBJiZP9pLPLF2NZM27ht1Lt7bVsEEV
    wCxQySAo72H6/sk6TkFZHIZvPBQIfTBJMODSnLaJCjYKbKl8q09w7ToO+qCGBDaT
    2xhOZSXYz8fbAbGUHQAcJbFNGW+z/+4v
    -----END PUBLIC KEY-----
```

Bob's static ECDH private key:

```
    -----BEGIN EC PRIVATE KEY-----
    MIGkAgEBBDAnJ4hB+tTUN9X03/W0RsrYy+qcptlRSYkhaDIsQYPXfTU0ugjJEmRk
    NTPj4y1IRjegBwYFK4EEACKhZANiAARJwY8E72eZTAauBsYSgVj0dH9sKjRbJ5j9
    149BWvBmbA3bIwmY7Z3WRYK8tPPxTtq2KfHIhF70JXnjJq7UpZT/BuSE8OfO5Ixi
    RynEwajfbPcl60SWhbloU6NrXe+/9bk=
    -----END EC PRIVATE KEY-----
```

Bob computes a shared secret, called Z, using the Alice's ephemeral
ECDH public key and his static ECDH private key; Z is:
    3f015ed0ff4b99523a95157bbe77e9cc0ee52fcffeb7e41eac79d1c11b6cc556
    19cf8807e6d800c2de40240fe0e26adc

Bob computes the pairwise key-encryption key, called KEK1, from Z
using the X9.63 KDF with the ECC-CMS-SharedInfo structure with the
values shown in B.1. The X9.63 KDF output is the 256-bit KEK1:
    27dc25ddb0b425f7a968ceada80a8f73c6ccaab115baafcce4a22a45d6b8f3da

Bob produces the 256-bit KEK2 with HKDF using SHA-384; the secret
value is KEK1; the 'info' is the DER-encoded CMSORIforPSKOtherInfo
structure with the values shown in B.1. The HKDF output is the
256-bit KEK2:
    7de693ee30ae22b5f8f6cd026c2164103f4e1430f1ab135dc1fb98954f9830bb

Bob uses AES-KEY-WRAP to decrypt the content-encryption key
with the KEK2; the content-encryption key is:
    937b1219a64d57ad81c05cc86075e86017848c824d4e85800c731c5b7b091033

Bob decrypts the content using AES-256-GCM with the content-
encryption key, and checks the received authentication tag. The
12-octet nonce used is:
    dbaddecaf888cafebabeface

The 12-octet authentication tag is:
    550260c42e5b29719426c1ff

The received ciphertext content is:
    fc6d6f823e3ed2d209d0c6ffcf

The resulting plaintext content is:
    48656c6c6f2c20776f726c6421
