Hash Of Root Key Certificate Extension draft-ietf-lamps-hash-of-root-key-cert-extn-00

Abstract

This document specifies the Hash Of Root Key certificate extension. This certificate extension is carried in the self-signed certificate for a trust anchor, which is often called a Root Certification Authority (CA) certificate. This certificate extension unambiguously identifies the next public key that will be used by the trust anchor.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of $\underline{\mathsf{BCP}}$ 78 and $\underline{\mathsf{BCP}}$ 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 4, 2019.

1. Introduction

This document specifies the Hash Of Root Key X.509 version 3 certificate extension. The extension is an optional addition to the Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile [RFC5280]. The certificate extension facilitates the orderly transition from one Root Certification Authority (CA) public key to the next. It does so by publishing the hash value of the next generation public key in the current self-signed certificate. This allows a relying party to unambiguously recognize the next generation public key when it becomes available.

A Root CA Certificate MAY include the Hashed Root Key certificate extension to provide the hash value of the next public key that will be used by the Root CA.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119][RFC8174] when, and only when, they appear in all capitals, as shown here.

1.2. ASN.1

Certificates [RFC5280] are generated using ASN.1 [\times 680], which uses the Basic Encoding Rules (BER) and the Distinguished Encoding Rules (DER) [\times 690].

2. Overview

Before the initial deployment of the Root CA, the following are generated:

R1 = The initial Root key pair

C1 = Self-signed certificate for R1, which also contains H2

R2 = The second generation Root key pair

H2 = Thumbprint (hash) of the public key of R2

C1 is a self-signed certificate, and it contains H2 within the HashOfRootKey extension. C1 is distributed as part of the initial the system deployment. The HashOfRootKey certificate extension is described in <u>Section 3</u>.

When the time comes to replace the initial Root CA certificate, R1, the following are generated:

R3 = The third generation Root key pair

H3 = Thumbprint (hash) the public key of R3

C2 = Self-signed certificate for R2, which contains H3

This is an iterative process. That is, R4 and H4 are generated when it is time for C3 to replace C2. And so on.

The successors to the Root CA self-signed certificate can be delivered by any means. Whenever a new Root CA certificate is received, the recipient is able to verify that the potential Root CA certificate chains back to a previously authenticated Root CA certificate with the hashOfRootKey certificate extension. That is, validate the self-signed signature and verify that the hash of the DER-encoded SubjectPublicKeyInfo from the potential Root CA certificate matches the value from the HashOfRootKey certificate extension of the current Root CA certificate. If the signature does not validate or the hash values do not match, then potential Root CA certificate is not a valid replacement, and the recipient continues to use the current Root CA certificate.

3. Hash Of Root Key Certificate Extension

The HashOfRootKey certificate extension MUST NOT be critical.

The following ASN.1 [\times 680][X690] syntax defines the HashOfRootKey certificate extension:

The definitions of EXTENSION and HashAlgorithm can be found in [RFC5912].

The hashAlg indicates the one-way hash algorithm that was used to compute the hash value.

The hashValue contains the hash value computed from the next generation public key. The public key is DER-encoded SubjectPublicKeyInfo as defined in [RFC5280].

4. IANA Considerations

This document makes no requests of the IANA.

5. Security Considerations

The security considerations from [RFC5280] apply, especially the discussion of self-issued certificates.

The Hash Of Root Key certificate extension facilitates the orderly transition from one Root CA public key to the next by publishing the hash value of the next generation public key in the current certificate. This allows a relying party to unambiguously recognize the next generation public key when it becomes available; however, the full public key is not disclosed until the Root CA releases the next generation certificate. In this way, attackers cannot begin to analyze the public key before the next generation Root CA certificate is released.

If an early release of the next generation public key occurs and the Root CA is concerned that attackers were given too much lead time to analyze that public key, then the Root CA can transition to a freshly generated key pair by rapidly performing two transitions. The first transition takes the Root CA to the key pair that suffered the early release, and it causes the Root CA to generate the subsequent Root key pair. The second transition occurs when the Root CA is confident

that the population of relying parties have completed the first transition, and it takes the Root CA to the freshly generated key pair. Of course, the second transition also causes the Root CA to generate the Root key pair for future use.

6. Acknowledgements

The Secure Electronic Transaction (SET) [SET] specification published by MasterCard and VISA in 1997 includes a very similar certificate extension. The SET certificate extension has essentially the same semantics, but the syntax fairly different.

CTIA - The Wireless Association is developing a public key infrastructure that will make use of the certificate extension described in this document.
