LDAP: The Protocol

Status of this Memo

This document is an Internet-Draft and is subject to all provisions of [section 3 of RFC 3667](#). By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she become aware will be disclosed, in accordance with [RFC 3668](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress".

The list of current Internet-Drafts can be accessed at [<http://www.ietf.org/ietf/1id-abstracts.txt>](http://www.ietf.org/ietf/1id-abstracts.txt).

The list of Internet-Draft Shadow Directories can be accessed at [<http://www.ietf.org/shadow.html>](http://www.ietf.org/shadow.html).

This Internet-Draft will expire in February 2005.

Technical discussion of this document will take place on the IETF LDAP Revision Working Group (LDAPbis) mailing list [<ietf-ldapbis@openldap.org>](mailto:ietf-ldapbis@openldap.org). Please send editorial comments directly to the editor [<jimse@novell.com>](mailto:jimse@novell.com).

Abstract

This document describes the protocol elements, along with their semantics and encodings, of the Lightweight Directory Access Protocol (LDAP). LDAP provides access to distributed directory services that act in accordance with X.500 data and service models. These protocol elements are based on those described in the X.500 Directory Access

Lightweight Directory Access Protocol Version 3

[1. Introduction](#)

The Directory is "a collection of open systems cooperating to provide directory services" [[X.500](#)]. A directory user, which may be a human or other entity, accesses the Directory through a client (or Directory User Agent (DUA)). The client, on behalf of the directory user, interacts with one or more servers (or Directory System Agents (DSA)). Clients interact with servers using a directory access protocol.

This document details the protocol elements of the Lightweight Directory Access Protocol (LDAP), along with their semantics. Following the description of protocol elements, it describes the way in which the protocol elements are encoded and transferred.

[1.1. Relationship to Other LDAP Specifications](#)

This document is an integral part of the LDAP Technical Specification [[Roadmap](#)] which obsoletes the previously defined LDAP technical specification, [RFC 3377](#), in its entirety.

This document obsoletes all of [RFC 2251](#) except the following: Sections [3.2](#), [3.4](#), [4.1.3](#) (last paragraph), 4.1.4, 4.1.5, 4.1.5.1, 4.1.9 (last paragraph), 5.1, 6.1, and 6.2 (last paragraph) are obsoleted by [[Models](#)].

[Section 3.3](#) is obsoleted by [[Roadmap](#)].

Sections [4.2.1](#) (portions), and 4.2.2 are obsoleted by [[AuthMeth](#)].

[Appendix C.1](#) summarizes substantive changes to the remaining sections.

This document obsoletes [RFC 2830](#), Sections [2](#) and [4](#) in entirety. The remainder of [RFC 2830](#) is obsoleted by [[AuthMeth](#)]. [Appendix C.2](#) summarizes substantive changes to the remaining sections.

This document also obsoletes [RFC 3771](#) in entirety.

2. Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", and "MAY" in this document are to be interpreted as described in [[Keyword](#)].

Character names in this document use the notation for code points and names from the Unicode Standard [[Unicode](#)]. For example, the letter "a" may be represented as either <U+0061> or <LATIN SMALL LETTER A>.

Note: a glossary of terms used in Unicode can be found in [[Glossary](#)]. Information on the Unicode character encoding model can be found in [[CharModel](#)].

Sermersheim

Internet-Draft - Expires May 2005

Page 3

Lightweight Directory Access Protocol Version 3

The term "transport connection" refers to the underlying transport services used to carry the protocol exchange, as well as associations established by these services.

The term "TLS layer" refers to TLS services used in providing security services, as well as associations established by these services.

The term "SASL layer" refers to SASL services used in providing security services, as well as associations established by these services.

The term "LDAP message layer" refers to the LDAP Message (PDU) services used in providing directory services, as well as associations established by these services.

The term "LDAP session" refers to combined services (transport connection, TLS layer, SASL layer, LDAP message layer) and their associations.

See the table in [Section 5](#) for an illustration of these four terms.

3. Protocol Model

The general model adopted by this protocol is one of clients performing protocol operations against servers. In this model, a client transmits a protocol request describing the operation to be performed to a server. The server is then responsible for performing the necessary operation(s) in the Directory. Upon completion of an

operation, the server typically returns a response containing appropriate data to the requesting client.

Protocol operations are generally independent of one another. Each operation is processed as an atomic action, leaving the directory in a consistent state.

Although servers are required to return responses whenever such responses are defined in the protocol, there is no requirement for synchronous behavior on the part of either clients or servers. Requests and responses for multiple operations generally may be exchanged between a client and server in any order. If required, synchronous behavior may be controlled by client applications.

The core protocol operations defined in this document can be mapped to a subset of the X.500 (1993) Directory Abstract Service [[X.511](#)]. However there is not a one-to-one mapping between LDAP operations and X.500 Directory Access Protocol (DAP) operations. Server implementations acting as a gateway to X.500 directories may need to make multiple DAP requests to service a single LDAP request.

[3.1](#) Operation and LDAP Message Layer Relationship

Sermersheim

Internet-Draft - Expires May 2005

Page 4

Lightweight Directory Access Protocol Version 3

Protocol operations are exchanged at the LDAP message layer. When the transport connection is closed, any uncompleted operations at the LDAP message layer, when possible, are abandoned, and when not possible, are completed without transmission of the response. Also, when the transport connection is closed, the client **MUST NOT** assume that any uncompleted update operations have succeeded or failed.

[4](#). Elements of Protocol

The protocol is described using Abstract Syntax Notation One ([[ASN.1](#)]), and is transferred using a subset of ASN.1 Basic Encoding Rules ([[BER](#)]). [Section 5](#) specifies how the protocol elements are encoded and transferred.

In order to support future extensions to this protocol, extensibility is implied where it is allowed per ASN.1 (i.e. sequence, set, choice, and enumerated types are extensible). In addition, ellipses (...) have been supplied in ASN.1 types that are explicitly extensible as discussed in [[LDAPIANA](#)]. Because of the implied extensibility, clients and servers **MUST** (unless otherwise specified) ignore trailing SEQUENCE components whose tags they do not recognize.

Changes to the protocol other than through the extension mechanisms described here require a different version number. A client indicates the version it is using as part of the BindRequest, described in [Section 4.2](#). If a client has not sent a Bind, the server MUST assume the client is using version 3 or later.

Clients may attempt to determine the protocol versions a server supports by reading the 'supportedLDAPVersion' attribute from the root DSE (DSA-Specific Entry) [[Models](#)].

[4.1](#). Common Elements

This section describes the LDAPMessage envelope Protocol Data Unit (PDU) format, as well as data type definitions, which are used in the protocol operations.

[4.1.1](#). Message Envelope

For the purposes of protocol exchanges, all protocol operations are encapsulated in a common envelope, the LDAPMessage, which is defined as follows:

```
LDAPMessage ::= SEQUENCE {  
    messageID      MessageID,  
    protocolOp     CHOICE {  
        bindRequest      BindRequest,  
        bindResponse     BindResponse,  
        unbindRequest    UnbindRequest,  
        searchRequest    SearchRequest,  
        ...  
    }
```

```
        searchResEntry    SearchResultEntry,  
        searchResDone     SearchResultDone,  
        searchResRef      SearchResultReference,  
        modifyRequest     ModifyRequest,  
        modifyResponse    ModifyResponse,  
        addRequest        AddRequest,  
        addResponse       AddResponse,  
        delRequest        DelRequest,  
        delResponse       DelResponse,  
        modDNRequest      ModifyDNRequest,  
        modDNResponse     ModifyDNResponse,  
        compareRequest    CompareRequest,  
        compareResponse   CompareResponse,  
        abandonRequest    AbandonRequest,  
        extendedReq       ExtendedRequest,  
        extendedResp      ExtendedResponse,  
        ...  
    }
```

```

        ...,
        intermediateResponse IntermediateResponse },
controls      [0] Controls OPTIONAL }

MessageID ::= INTEGER (0 .. maxInt)

maxInt INTEGER ::= 2147483647 -- (231 - 1) --

```

The ASN.1 type Controls is defined in [Section 4.1.11](#).

The function of the LDAPMessage is to provide an envelope containing common fields required in all protocol exchanges. At this time the only common fields are the messageID and the controls.

If the server receives a PDU from the client in which the LDAPMessage SEQUENCE tag cannot be recognized, the messageID cannot be parsed, the tag of the protocolOp is not recognized as a request, or the encoding structures or lengths of data fields are found to be incorrect, then the server SHOULD return the Notice of Disconnection described in [Section 4.4.1](#), with the resultCode set to protocolError, and MUST immediately close the transport connection.

In other cases where the client or server cannot parse a PDU, it SHOULD abruptly close the transport connection where further communication (including providing notice) would be pernicious. Otherwise, server implementations MUST return an appropriate response to the request, with the resultCode set to protocolError.

[4.1.1.1](#). Message ID

All LDAPMessage envelopes encapsulating responses contain the messageID value of the corresponding request LDAPMessage.

The message ID of a request MUST have a non-zero value different from the messageID of any other request in progress in the same LDAP

session. The zero value is reserved for the unsolicited notification message.

Typical clients increment a counter for each request.

A client MUST NOT send a request with the same message ID as an earlier request in the same LDAP session unless it can be determined that the server is no longer servicing the earlier request (e.g. after the final response is received, or a subsequent Bind

completes). Otherwise the behavior is undefined. For this purpose, note that Abandon and successfully abandoned operations do not send responses.

4.1.2. String Types

The LDAPString is a notational convenience to indicate that, although strings of LDAPString type encode as ASN.1 OCTET STRING types, the [\[ISO10646\]](#) character set (a superset of [\[Unicode\]](#)) is used, encoded following the [\[UTF-8\]](#) algorithm. Note that Unicode characters U+0000 through U+007F are the same as ASCII 0 through 127, respectively, and have the same single octet UTF-8 encoding. Other Unicode characters have a multiple octet UTF-8 encoding.

```
LDAPString ::= OCTET STRING -- UTF-8 encoded,  
                        -- \[ISO10646\] characters
```

The LDAPOID is a notational convenience to indicate that the permitted value of this string is a (UTF-8 encoded) dotted-decimal representation of an OBJECT IDENTIFIER. Although an LDAPOID is encoded as an OCTET STRING, values are limited to the definition of <numericoid> given in Section 1.4 of [\[Models\]](#).

```
LDAPOID ::= OCTET STRING -- Constrained to <numericoid> \[Models\]
```

For example,

```
1.3.6.1.4.1.1466.1.2.3
```

4.1.3. Distinguished Name and Relative Distinguished Name

An LDAPDN is defined to be the representation of a Distinguished Name (DN) after encoding according to the specification in [\[LDAPDN\]](#).

```
LDAPDN ::= LDAPString  
        -- Constrained to <distinguishedName> \[LDAPDN\]
```

A RelativeLDAPDN is defined to be the representation of a Relative Distinguished Name (RDN) after encoding according to the specification in [\[LDAPDN\]](#).

```
RelativeLDAPDN ::= LDAPString  
                -- Constrained to <name-component> \[LDAPDN\]
```

[4.1.4.](#) Attribute Descriptions

The definition and encoding rules for attribute descriptions are defined in Section 2.5 of [[Models](#)]. Briefly, an attribute description is an attribute type and zero or more options.

```
AttributeDescription ::= LDAPString
                        -- Constrained to <attributedescription>
                        -- [Models]
```

[4.1.5.](#) Attribute Value

A field of type AttributeValue is an OCTET STRING containing an encoded attribute value. The attribute value is encoded according to the LDAP-specific encoding definition of its corresponding syntax. The LDAP-specific encoding definitions for different syntaxes and attribute types may be found in other documents and in particular [[Syntaxes](#)].

```
AttributeValue ::= OCTET STRING
```

Note that there is no defined limit on the size of this encoding; thus protocol values may include multi-megabyte attribute values (e.g. photographs).

Attribute values may be defined which have arbitrary and non-printable syntax. Implementations MUST NOT display nor attempt to decode an attribute value if its syntax is not known. The implementation may attempt to discover the subschema of the source entry, and retrieve the descriptions of 'attributeTypes' from it [[Models](#)].

Clients MUST only send attribute values in a request that are valid according to the syntax defined for the attributes.

[4.1.6.](#) Attribute Value Assertion

The AttributeValueAssertion (AVA) type definition is similar to the one in the X.500 Directory standards. It contains an attribute description and a matching rule ([[Models](#)] [Section 4.1.3](#)) assertion value suitable for that type. Elements of this type are typically used to assert that the value in assertionValue matches a value of an attribute.

```
AttributeValueAssertion ::= SEQUENCE {
    attributeDesc  AttributeDescription,
    assertionValue AssertionValue }
```

```
AssertionValue ::= OCTET STRING
```

Lightweight Directory Access Protocol Version 3

The syntax of the AssertionValue depends on the context of the LDAP operation being performed. For example, the syntax of the EQUALITY matching rule for an attribute is used when performing a Compare operation. Often this is the same syntax used for values of the attribute type, but in some cases the assertion syntax differs from the value syntax. See objectIdentifierFirstComponentMatch in [\[Syntaxes\]](#) for an example.

[4.1.7.](#) Attribute and PartialAttribute

Attributes and partial attributes consist of an attribute description and attribute values. A PartialAttribute allows zero values, while Attribute requires at least one value.

```
PartialAttribute ::= SEQUENCE {  
    type      AttributeDescription,  
    vals      SET OF value AttributeValue }  
  
Attribute ::= PartialAttribute(WITH COMPONENTS {  
    ...,  
    vals (SIZE(1..MAX))})
```

No two of the attribute values may be equivalent as described by Section 2.3 of [\[Models\]](#). The set of attribute values is unordered. Implementations MUST NOT rely upon the ordering being repeatable.

[4.1.8.](#) Matching Rule Identifier

Matching rules are defined in Section 4.1.3 of [\[Models\]](#). A matching rule is identified in the protocol by the printable representation of either its <numericoid>, or one of its short name descriptors [\[Models\]](#), e.g. 'caseIgnoreMatch' or '2.5.13.2'.

```
MatchingRuleId ::= LDAPString
```

[4.1.9.](#) Result Message

The LDAPResult is the construct used in this protocol to return success or failure indications from servers to clients. To various requests, servers will return responses containing the elements found in LDAPResult to indicate the final status of the protocol operation request.

```
LDAPResult ::= SEQUENCE {
```

```

resultCode      ENUMERATED {
    success              (0),
    operationsError      (1),
    protocolError        (2),
    timeLimitExceeded    (3),
    sizeLimitExceeded    (4),
    compareFalse         (5),

```

Lightweight Directory Access Protocol Version 3

```

    compareTrue          (6),
    authMethodNotSupported (7),
    strongAuthRequired    (8),
    -- 9 reserved --
    referral              (10),
    adminLimitExceeded    (11),
    unavailableCriticalExtension (12),
    confidentialityRequired (13),
    saslBindInProgress    (14),
    noSuchAttribute        (16),
    undefinedAttributeType (17),
    inappropriateMatching (18),
    constraintViolation    (19),
    attributeOrValueExists (20),
    invalidAttributeSyntax (21),
    -- 22-31 unused --
    noSuchObject          (32),
    aliasProblem           (33),
    invalidDNSSyntax      (34),
    -- 35 reserved for undefined isLeaf --
    aliasDereferencingProblem (36),
    -- 37-47 unused --
    inappropriateAuthentication (48),
    invalidCredentials      (49),
    insufficientAccessRights (50),
    busy                    (51),

    loopDetect              (54),
    -- 55-63 unused --
    namingViolation        (64),
    objectClassViolation    (65),
    notAllowedOnNonLeaf     (66),
    notAllowedOnRDN         (67),
    entryAlreadyExists      (68),
    objectClassModsProhibited (69),
    -- 70 reserved for CLDAP --
    affectsMultipleDSAs     (71),
    -- 72-79 unused --

```

```

        other                                (80),
        ... },
    matchedDN                                LDAPDN,
    diagnosticMessage                        LDAPString,
    referral                                [3] Referral OPTIONAL }

```

The resultCode enumeration is extensible as defined in Section 3.6 of [\[LDAPIANA\]](#). The meanings of the listed result codes are given in [Appendix A](#). If a server detects multiple errors for an operation, only one result code is returned. The server should return the result code that best indicates the nature of the error encountered.

The diagnosticMessage field of this construct may, at the server's option, be used to return a string containing a textual, human-readable (terminal control and page formatting characters should be

Sermersheim Internet-Draft - Expires May 2005 Page 10

Lightweight Directory Access Protocol Version 3

avoided) diagnostic message. As this diagnostic message is not standardized, implementations MUST NOT rely on the values returned. Diagnostic messages typically supplement the resultCode with additional information. If the server chooses not to return a textual diagnostic, the diagnosticMessage field MUST be empty.

For certain result codes (typically, but not restricted to noSuchObject, aliasProblem, invalidDNSyntax and aliasDereferencingProblem), the matchedDN field is set (subject to access controls) to the name of the last entry (object or alias) used in finding the target (or base) object. This will be a truncated form of the provided name or, if an alias was dereferenced while attempting to locate the entry, of the resulting name. Otherwise the matchedDN field is empty.

[4.1.10](#). Referral

The referral result code indicates that the contacted server cannot or will not perform the operation and that one or more other servers may be able to. Reasons for this include:

- The target entry of the request is not held locally, but the server has knowledge of its possible existence elsewhere.
- The operation is restricted on this server -- perhaps due to a read-only copy of an entry to be modified.

The referral field is present in an LDAPResult if the resultCode is set to referral, and absent with all other result codes. It contains one or more references to one or more servers or services that may be accessed via LDAP or other protocols. Referrals can be returned in

response to any operation request (except Unbind and Abandon which do not have responses). At least one URI MUST be present in the Referral.

During a Search operation, after the baseObject is located, and entries are being evaluated, the referral is not returned. Instead, continuation references, described in [Section 4.5.3](#), are returned when other servers would need to be contacted to complete the operation.

Referral ::= SEQUENCE SIZE (1..MAX) OF uri URI

URI ::= LDAPString -- limited to characters permitted in
 -- URIs

If the client wishes to progress the operation, it contacts one of the supported services found in the referral. If multiple URIs are present, the client assumes that any supported URI may be used to progress the operation.

Protocol peers that follow referrals MUST ensure that they do not loop between servers. They MUST NOT repeatedly contact the same

Sermersheim Internet-Draft - Expires May 2005 Page 11

Lightweight Directory Access Protocol Version 3

server for the same request with the same parameters. Some implementations use a counter that is incremented each time referral handling occurs for an operation, and these kinds of implementations MUST be able to handle at least ten nested referrals between the root and a leaf entry.

A URI for a server implementing LDAP and accessible via [[TCP](#)]/[[IP](#)] (v4 or v6) is written as an LDAP URL according to [[LDAPURL](#)].

Referral values which are LDAP URLs follow these rules:

- If an alias was dereferenced, the <dn> part of the URL MUST be present, with the new target object name.
- It is RECOMMENDED that the <dn> part be present to avoid ambiguity.
- If the <dn> part is present, the client uses this name in its next request to progress the operation, and if it is not present the client uses the same name as in the original request.
- Some servers (e.g. participating in distributed indexing) may provide a different filter in a URL of a referral for a Search operation.

- If the <filter> part of the LDAP URL is present, the client uses this filter in its next request to progress this Search, and if it is not present the client uses the same filter as it used for that Search.
- For Search, it is RECOMMENDED that the <scope> part be present to avoid ambiguity.
- If the <scope> part is missing, the scope of the original Search is used by the client to progress the operation.
- Other aspects of the new request may be the same as or different from the request which generated the referral.

Other kinds of URIs may be returned. The syntax and semantics of such URIs is left to future specifications. Clients may ignore URIs that they do not support.

UTF-8 encoded characters appearing in the string representation of a DN, search filter, or other fields may not be legal for URLs (e.g. spaces) and MUST be escaped using the % method in [[URI](#)].

4.1.11. Controls

Controls provide a mechanism whereby the semantics and arguments of existing LDAP operations may be extended. One or more controls may be attached to a single LDAP message. A control only affects the semantics of the message it is attached to.

Sermersheim Internet-Draft - Expires May 2005 Page 12

Lightweight Directory Access Protocol Version 3

Controls sent by clients are termed 'request controls' and those sent by servers are termed 'response controls'.

Controls ::= SEQUENCE OF control Control

```
Control ::= SEQUENCE {
    controlType          LDAPOID,
    criticality          BOOLEAN DEFAULT FALSE,
    controlValue         OCTET STRING OPTIONAL }
```

The controlType field is the dotted-decimal representation of an OBJECT IDENTIFIER which uniquely identifies the control. This provides unambiguous naming of controls. Often, response control(s) solicited by a request control share controlType values with the request control.

The criticality field only has meaning in controls attached to

request messages (except UnbindRequest). For controls attached to response messages and the UnbindRequest, the criticality field SHOULD be FALSE, and MUST be ignored by the receiving protocol peer. A value of TRUE indicates that it is unacceptable to perform the operation without applying the semantics of the control. Specifically, the criticality field is applied as follows:

- Regardless of the value of the criticality field, if the server recognizes the control type and it is appropriate for the operation, the server is to make use of the control when performing the operation.
- If the server does not recognize the control type or it is not appropriate for the operation, and the criticality field is TRUE, the server MUST NOT perform the operation, and for operations that have a response message, MUST return with the resultCode set to unavailableCriticalExtension.
- If the server does not recognize the control type or it is not appropriate for the operation, and the criticality field is FALSE, the server MUST ignore the control.

The controlValue may contain information associated with the controlType. Its format is defined by the specification of the control. Implementations MUST be prepared to handle arbitrary contents of the controlValue octet string, including zero bytes. It is absent only if there is no value information which is associated with a control of its type. When a controlValue is defined in terms of ASN.1, and BER encoded according to [Section 5.1](#), it also follows the extensibility rules in [Section 4](#).

Servers list the controlType of request controls they recognize in the 'supportedControl' attribute in the root DSE (Section 5.1 of [\[Models\]](#)).

Lightweight Directory Access Protocol Version 3

Controls SHOULD NOT be combined unless the semantics of the combination has been specified. The semantics of control combinations, if specified, are generally found in the control specification most recently published. When a combination of controls is encountered whose semantics are invalid, not specified (or not known), the message is considered to be not well-formed, thus the operation fails with protocolError. Additionally, unless order-dependent semantics are given in a specification, the order of a combination of controls in the SEQUENCE is ignored. Where the order is to be ignored but cannot be ignored by the server, the message is considered not well-formed and the operation fails with

protocolError.

This document does not specify any controls. Controls may be specified in other documents. Documents detailing control extensions are to provide for each control:

- the OBJECT IDENTIFIER assigned to the control,
- direction as to what value the sender should provide for the criticality field (note: the semantics of the criticality field are defined above should not be altered by the control's specification),
- whether the controlValue field is present, and if so, the format of its contents,
- the semantics of the control, and
- optionally, semantics regarding the combination of the control with other controls.

4.2. Bind Operation

The function of the Bind operation is to allow authentication information to be exchanged between the client and server. The Bind operation should be thought of as the "authenticate" operation. Operational, authentication, and security-related semantics of this operation are given in [[AuthMeth](#)].

The Bind request is defined as follows:

```
BindRequest ::= [APPLICATION 0] SEQUENCE {  
    version          INTEGER (1 .. 127),  
    name             LDAPDN,  
    authentication   AuthenticationChoice }  
  
AuthenticationChoice ::= CHOICE {  
    simple           [0] OCTET STRING,  
                   -- 1 and 2 reserved  
    sasl             [3] SaslCredentials,  
    ... }  

```

```
SaslCredentials ::= SEQUENCE {  
    mechanism        LDAPString,  
    credentials      OCTET STRING OPTIONAL }  

```

Fields of the BindRequest are:

- version: A version number indicating the version of the protocol to be used at the LDAP message layer. This document describes version 3 of the protocol. There is no version negotiation. The client sets this field to the version it desires. If the server does not support the specified version, it MUST respond with a BindResponse where the resultCode is set to protocolError.
- name: If not empty, the name of the Directory object that the client wishes to bind as. This field may take on a null value (a zero length string) for the purposes of anonymous binds ([AuthMeth] [Section 5.1](#)) or when using Simple Authentication and Security Layer [SASL] authentication ([AuthMeth] [Section 3.3.2](#)). Where the server attempts to locate the named object, it SHALL NOT perform alias dereferencing.
- authentication: information used in authentication. This type is extensible as defined in Section 3.7 of [LDAPIANA]. Servers that do not support a choice supplied by a client return a BindResponse with the resultCode set to authMethodNotSupported.

Textual passwords (consisting of a character sequence with a known character set and encoding) transferred to the server using the simple AuthenticationChoice SHALL be transferred as [UTF-8] encoded [Unicode]. Prior to transfer, clients SHOULD prepare text passwords by applying the [SASLprep] profile of the [Stringprep] algorithm. Passwords consisting of other data (such as random octets) MUST NOT be altered. The determination of whether a password is textual is a local client matter.

[4.2.1](#). Processing of the Bind Request

Before processing a BindRequest, all uncompleted operations MUST either complete or be abandoned. The server may either wait for the uncompleted operations to complete, or abandon them. The server then proceeds to authenticate the client in either a single-step, or multi-step Bind process. Each step requires the server to return a BindResponse to indicate the status of authentication.

After sending a BindRequest, clients MUST NOT send further LDAP PDUs until receiving the BindResponse. Similarly, servers SHOULD NOT process or respond to requests received while processing a BindRequest.

If the client did not bind before sending a request and receives an operationsError to that request, it may then send a BindRequest. If this also fails or the client chooses not to bind on the existing LDAP session, it may close the transport connection, reopen it and

Lightweight Directory Access Protocol Version 3

begin again by first sending a PDU with a BindRequest. This will aid in interoperating with servers implementing other versions of LDAP.

Clients may send multiple Bind requests to change the authentication and/or security associations or to complete a multi-stage Bind process. Authentication from earlier binds is subsequently ignored.

For some SASL authentication mechanisms, it may be necessary for the client to invoke the BindRequest multiple times ([\[AuthMeth\]](#) [Section 8.2](#)). Clients MUST NOT invoke operations between two Bind requests made as part of a multi-stage Bind.

A client may abort a SASL bind negotiation by sending a BindRequest with a different value in the mechanism field of SaslCredentials, or an AuthenticationChoice other than sasl.

If the client sends a BindRequest with the sasl mechanism field as an empty string, the server MUST return a BindResponse with the resultCode set to authMethodNotSupported. This will allow clients to abort a negotiation if it wishes to try again with the same SASL mechanism.

[4.2.2](#). Bind Response

The Bind response is defined as follows.

```
BindResponse ::= [APPLICATION 1] SEQUENCE {  
    COMPONENTS OF LDAPResult,  
    serverSaslCreds    [7] OCTET STRING OPTIONAL }
```

BindResponse consists simply of an indication from the server of the status of the client's request for authentication.

A successful Bind operation is indicated by a BindResponse with a resultCode set to success. Otherwise, an appropriate result code is set in the BindResponse. For BindResponse, the protocolError result code may be used to indicate that the version number supplied by the client is unsupported.

If the client receives a BindResponse where the resultCode is set to protocolError, it is to assume that the server does not support this version of LDAP. While the client may be able proceed with another version of this protocol (this may or may not require closing and re-establishing the transport connection), how to proceed with another version of this protocol is beyond the scope of this document. Clients which are unable or unwilling to proceed SHOULD close the transport connection.

The serverSaslCreds field is used as part of a SASL-defined bind mechanism to allow the client to authenticate the server to which it is communicating, or to perform "challenge-response" authentication. If the client bound with the simple choice, or the SASL mechanism

Lightweight Directory Access Protocol Version 3

does not require the server to return information to the client, then this field SHALL NOT be included in the BindResponse.

4.3. Unbind Operation

The function of the Unbind operation is to terminate an LDAP session. The Unbind operation is not the antithesis of the Bind operation as the name implies. The naming of these operations are historical. The Unbind operation should be thought of as the "quit" operation.

The Unbind operation is defined as follows:

UnbindRequest ::= [APPLICATION 2] NULL

The client, upon transmission of the UnbindRequest, and the server, upon receipt of the UnbindRequest are to close the LDAP session as follows:

- cease exchanges at the LDAP message layer,
- close the SASL layer (if installed),
- close the TLS layer (if installed), and
- close the transport connection.

Uncompleted operations are handled as specified in [Section 5.1](#).

4.4. Unsolicited Notification

An unsolicited notification is an LDAPMessage sent from the server to the client which is not in response to any LDAPMessage received by the server. It is used to signal an extraordinary condition in the server or in the LDAP session between the client and the server. The notification is of an advisory nature, and the server will not expect any response to be returned from the client.

The unsolicited notification is structured as an LDAPMessage in which the messageID is zero and protocolOp is set to the extendedResp choice using the ExtendedResponse type (See [Section 4.12](#)). The responseName field of the ExtendedResponse always contains an LDAPOID which is unique for this notification.

One unsolicited notification (Notice of Disconnection) is defined in this document. The specification of an unsolicited notification consists of:

- the OBJECT IDENTIFIER assigned to the notification (to be specified in the responseName,
- the format of the contents of the responseValue (if any),
- the circumstances which will cause the notification to be sent, and

Lightweight Directory Access Protocol Version 3

- the semantics of the message.

4.4.1. Notice of Disconnection

This notification may be used by the server to advise the client that the server is about to close the transport connection on its own initiative. This notification is intended to assist clients in distinguishing between an exceptional server condition and a transient network failure. Note that this notification is not a response to an Unbind requested by the client. Uncompleted operations are handled as specified in [Section 5.1](#).

The responseName is 1.3.6.1.4.1.1466.20036, the responseValue field is absent, and the resultCode is used to indicate the reason for the disconnection. When the strongAuthRequired resultCode is returned with this message, it indicates that the server has detected that an established security association between the client and server has unexpectedly failed or been compromised.

Upon transmission of the Notice of Disconnection, the server MUST cease transmission of messages to the client, and MUST close the transport connection.

4.5. Search Operation

The Search operation is used to request a server to return, subject to access controls and other restrictions, a set of entries matching a complex search criterion. This can be used to read attributes from a single entry, from entries immediately subordinate to a particular entry, or a whole subtree of entries.

4.5.1. Search Request

The Search request is defined as follows:

```
SearchRequest ::= [APPLICATION 3] SEQUENCE {
    baseObject      LDAPDN,
    scope           ENUMERATED {
        baseObject      (0),
        singleLevel     (1),
        wholeSubtree    (2),
        ... },
    derefAliases    ENUMERATED {
        neverDerefAliases (0),
        derefInSearching  (1),
        derefFindingBaseObj (2),
        derefAlways       (3) },
    sizeLimit       INTEGER (0 .. maxInt),
    timeLimit       INTEGER (0 .. maxInt),
    typesOnly       BOOLEAN,
    filter          Filter,
```

Sermersheim

Internet-Draft - Expires May 2005

Page 18

Lightweight Directory Access Protocol Version 3

```
attributes      AttributeSelection }
```

```
AttributeSelection ::= SEQUENCE OF selector LDAPString
    -- The LDAPString is constrained to
    -- <attributeSelector> below
```

```
Filter ::= CHOICE {
    and          [0] SET SIZE (1..MAX) OF filter Filter,
    or           [1] SET SIZE (1..MAX) OF filter Filter,
    not          [2] Filter,
    equalityMatch [3] AttributeValueAssertion,
    substrings   [4] SubstringFilter,
    greaterOrEqual [5] AttributeValueAssertion,
    lessOrEqual  [6] AttributeValueAssertion,
    present      [7] AttributeDescription,
    approxMatch  [8] AttributeValueAssertion,
    extensibleMatch [9] MatchingRuleAssertion,
    ... }
```

```
SubstringFilter ::= SEQUENCE {
    type          AttributeDescription,
    substrings     SEQUENCE SIZE (1..MAX) OF substring CHOICE {
        initial [0] AssertionValue, -- can occur at most once
        any     [1] AssertionValue,
        final   [2] AssertionValue } -- can occur at most once
    }
```

```

MatchingRuleAssertion ::= SEQUENCE {
    matchingRule      [1] MatchingRuleId OPTIONAL,
    type              [2] AttributeDescription OPTIONAL,
    matchValue        [3] AssertionValue,
    dnAttributes      [4] BOOLEAN DEFAULT FALSE }

```

Note that an X.500 "list"-like operation can be emulated by the client requesting a singleLevel Search operation with a filter checking for the presence of the 'objectClass' attribute, and that an X.500 "read"-like operation can be emulated by a baseObject Search operation with the same filter. A server which provides a gateway to X.500 is not required to use the Read or List operations, although it may choose to do so, and if it does, it must provide the same semantics as the X.500 Search operation.

4.5.1.1 SearchRequest.baseObject

The name of the base object entry (or possibly the root) relative to which the Search is to be performed.

4.5.1.2 SearchRequest.scope

Specifies the scope of the Search to be performed. The semantics (as described in [[X.511](#)]) of the possible values of this field are:

Sermersheim Internet-Draft - Expires May 2005 Page 19

Lightweight Directory Access Protocol Version 3

baseObject: The scope is constrained to the entry named by baseObject.

singleLevel: The scope is constrained to the immediate subordinates of the entry named by baseObject.

wholeSubtree: the scope is constrained to the entry named by the baseObject, and all its subordinates.

4.5.1.3 SearchRequest.derefAliases

An indicator as to how alias entries (as defined in [[Models](#)]) are to be handled in searching. The semantics of the defined values of this field are:

neverDerefAliases: Do not dereference aliases in searching or in locating the base object of the Search.

derefInSearching: While searching subordinates of the base object,

dereference any alias within the search scope (the act of dereferencing an alias includes recursively dereferencing aliases which refer to aliases). Dereferenced objects become the vertices of further search scopes where the Search operation continues. If the search scope is wholeSubtree, the Search continues in the subtree(s) of any dereferenced object. If the search scope is singleLevel, the search is applied to any dereferenced objects, and is not applied to their subordinates. Servers SHOULD eliminate duplicate entries that arise due to alias dereferencing while searching.

derefFindingBaseObj: Dereference aliases in locating the base object of the Search, but not when searching subordinates of the base object.

derefAlways: Dereference aliases both in searching and in locating the base object of the Search.

Servers MUST detect looping while dereferencing aliases in order to prevent denial of service attacks of this nature.

4.5.1.4 SearchRequest.sizeLimit

A size limit that restricts the maximum number of entries to be returned as a result of the Search. A value of zero in this field indicates that no client-requested size limit restrictions are in effect for the Search. Servers may also enforce a maximum number of entries to return.

4.5.1.5 SearchRequest.timeLimit

A time limit that restricts the maximum time (in seconds) allowed for a Search. A value of zero in this field indicates that no client-requested time limit restrictions are in effect for the Search. Servers may also enforce a maximum time limit for the Search.

4.5.1.6 SearchRequest.typesOnly

An indicator as to whether Search results are to contain both attribute descriptions and values, or just attribute descriptions. Setting this field to TRUE causes only attribute descriptions (no values) to be returned. Setting this field to FALSE causes both attribute descriptions and values to be returned.

[4.5.1.7](#) SearchRequest.filter

A filter that defines the conditions that must be fulfilled in order for the Search to match a given entry.

The 'and', 'or' and 'not' choices can be used to form combinations of filters. At least one filter element MUST be present in an 'and' or 'or' choice. The others match against individual attribute values of entries in the scope of the Search. (Implementor's note: the 'not' filter is an example of a tagged choice in an implicitly-tagged module. In BER this is treated as if the tag was explicit.)

A server MUST evaluate filters according to the three-valued logic of [\[X.511\]](#) (1993) Clause 7.8.1. In summary, a filter is evaluated to either "TRUE", "FALSE" or "Undefined". If the filter evaluates to TRUE for a particular entry, then the attributes of that entry are returned as part of the Search result (subject to any applicable access control restrictions). If the filter evaluates to FALSE or Undefined, then the entry is ignored for the Search.

A filter of the "and" choice is TRUE if all the filters in the SET OF evaluate to TRUE, FALSE if at least one filter is FALSE, and otherwise Undefined. A filter of the "or" choice is FALSE if all of the filters in the SET OF evaluate to FALSE, TRUE if at least one filter is TRUE, and Undefined otherwise. A filter of the 'not' choice is TRUE if the filter being negated is FALSE, FALSE if it is TRUE, and Undefined if it is Undefined.

A filter item evaluates to Undefined when the server would not be able to determine whether the assertion value matches an entry. Examples include:

- An attribute description in an equalityMatch, substrings, greaterOrEqual, lessOrEqual, approxMatch or extensibleMatch filter is not recognized by the server.
- The attribute type does not define the appropriate matching rule.

Lightweight Directory Access Protocol Version 3

- A MatchingRuleId in the extensibleMatch is not recognized by the server or is not valid for the attribute type.
- The type of filtering requested is not implemented.
- The assertion value is invalid.

For example, if a server did not recognize the attribute type shoeSize, a filter of (shoeSize=*) would evaluate to FALSE, and the filters (shoeSize=12), (shoeSize>=12) and (shoeSize<=12) would each evaluate to Undefined.

Servers MUST NOT return errors if attribute descriptions or matching rule ids are not recognized, assertion values are invalid, or the assertion syntax is not supported. More details of filter processing are given in Clause 7.8 of [[X.511](#)].

[4.5.1.7.1](#) SearchRequest.filter.equalityMatch

The matching rule for equalityMatch filter items is defined by the EQUALITY matching rule for the attribute type.

[4.5.1.7.2](#) SearchRequest.filter.substrings

There SHALL be at most one 'initial', and at most one 'final' in the 'substrings' of a SubstringFilter. If 'initial' is present, it SHALL be the first element of 'substrings'. If 'final' is present, it SHALL be the last element of 'substrings'.

The matching rule for an AssertionValue in a substrings filter item is defined by the SUBSTR matching rule for the attribute type. Note that the AssertionValue in a substrings filter item conforms to the assertion syntax of the EQUALITY matching rule for the attribute type rather than the assertion syntax of the SUBSTR matching rule for the attribute type. Conceptually, the entire SubstringFilter is converted into an assertion value of the substrings matching rule prior to applying the rule.

[4.5.1.7.3](#) SearchRequest.filter.greaterOrEqual

The matching rule for the greaterOrEqual filter item is defined by the ORDERING and EQUALITY matching rules for the attribute type.

[4.5.1.7.4](#) SearchRequest.filter.lessOrEqual

The matching rule for the lessOrEqual filter item is defined by the ORDERING matching rule for the attribute type.

[4.5.1.7.5](#) SearchRequest.filter.present

The present match evaluates to TRUE where there is an attribute or subtype of the specified attribute description present in an entry, and FALSE otherwise (including a presence test with an unrecognized attribute description).

4.5.1.7.6 SearchRequest.filter.approxMatch

An approxMatch filter item evaluates to TRUE when there is a value of the attribute or subtype for which some locally-defined approximate matching algorithm (e.g. spelling variations, phonetic match, etc.) returns TRUE. If an item matches for equality, it also satisfies an approximate match. If approximate matching is not supported for the attribute, this filter item should be treated as an equalityMatch.

4.5.1.7.7 SearchRequest.filter.extensibleMatch

The fields of the extensibleMatch filter item are evaluated as follows:

- If the matchingRule field is absent, the type field MUST be present, and an equality match is performed for that type.
- If the type field is absent and the matchingRule is present, the matchValue is compared against all attributes in an entry which support that matchingRule.
- If the type field is present and the matchingRule is present, the matchValue is compared against entry attributes of the specified type.
- If the dnAttributes field is set to TRUE, the match is additionally applied against all the AttributeValueAssertions in an entry's distinguished name, and evaluates to TRUE if there is at least one attribute in the distinguished name for which the filter item evaluates to TRUE. The dnAttributes field is present to alleviate the need for multiple versions of generic matching rules (such as word matching), where one applies to entries and another applies to entries and DN attributes as well.

The matchingRule used for evaluation determines the syntax for the assertion value. Once the matchingRule and attribute(s) have been determined, the filter item evaluates to TRUE if it matches with at least one attribute in the entry, FALSE if it does not match any attribute in the entry, and Undefined if the matchingRule is not recognized, the matchingRule is unsuitable for use with the specified type, or the assertionValue is invalid.

4.5.1.7 SearchRequest.attributes

Lightweight Directory Access Protocol Version 3

A selection list of the attributes to be returned from each entry which matches the search filter. LDAPString values of this field are constrained to the following Augmented Backus-Naur Form ([\[ABNF\]](#)):

attributeSelector = attributedescription / selectorpecial

selectorspecial = noattrs / alluserattrs

noattrs = %x31.2E.31 ; "1.1"

alluserattrs = %x2A ; asterisk ("*)

The <attributedescription> production is defined in Section 2.5 of [\[Models\]](#).

There are three special cases which may appear in the attributes selection list:

- an empty list with no attributes,
- a list containing "*" (with zero or more attribute descriptions), and
- a list containing only "1.1".

An empty list requests the return of all user attributes.

A list containing "*" requests the return of all user attributes in addition to other listed (operational) attributes.

A list containing only the OID "1.1" indicates that no attributes are to be returned. If "1.1" is provided with other attributeSelector values, the "1.1" attributeSelector is ignored. This OID was chosen because it does not (and can not) correspond to any attribute in use.

Client implementors should note that even if all user attributes are requested, some attributes and/or attribute values of the entry may not be included in Search results due to access controls or other restrictions. Furthermore, servers will not return operational attributes, such as objectClasses or attributeTypes, unless they are listed by name. Operational attributes are described in [\[Models\]](#).

Attributes are returned at most once in an entry. If an attribute description is named more than once in the list, the subsequent names

are ignored. If an attribute description in the list is not recognized, it is ignored by the server.

4.5.2. Search Result

The results of the Search operation are returned as zero or more SearchResultEntry and/or zero or more SearchResultReference messages, followed by a single SearchResultDone message.

Sermersheim

Internet-Draft - Expires May 2005

Page 24

Lightweight Directory Access Protocol Version 3

```
SearchResultEntry ::= [APPLICATION 4] SEQUENCE {  
    objectName      LDAPDN,  
    attributes      PartialAttributeList }
```

```
PartialAttributeList ::= SEQUENCE OF  
    partialAttribute PartialAttribute  
-- Note that the PartialAttributeList may hold zero elements.  
-- This may happen when none of the attributes of an entry  
-- were requested, or could be returned.  
-- Note also that the partialAttribute vals set may hold zero  
-- elements. This may happen when typesOnly is requested, access  
-- controls prevent the return of values, or other reasons.
```

```
SearchResultReference ::= [APPLICATION 19] SEQUENCE  
    SIZE (1..MAX) OF uri URI
```

```
SearchResultDone ::= [APPLICATION 5] LDAPResult
```

Each SearchResultEntry represents an entry found during the Search. Each SearchResultReference represents an area not yet explored during the Search. The SearchResultEntry and SearchResultReference PDUs may come in any order. Following all the SearchResultReference and SearchResultEntry responses, the server returns a SearchResultDone response, which contains an indication of success, or detailing any errors that have occurred.

Each entry returned in a SearchResultEntry will contain all appropriate attributes as specified in the attributes field of the Search Request, subject to access control and other administrative policy.

Some attributes may be constructed by the server and appear in a SearchResultEntry attribute list, although they are not stored attributes of an entry. Clients SHOULD NOT assume that all attributes can be modified, even if permitted by access control.

If the server's schema defines short names [[Models](#)] for an attribute

type then the server SHOULD use one of those names in attribute descriptions for that attribute type (in preference to using the <numericoid> [\[Models\]](#) format of the attribute type's object identifier). The server SHOULD NOT use the short name if that name is known by the server to be ambiguous, or otherwise likely to cause interoperability problems.

[4.5.3. Continuation References in the Search Result](#)

If the server was able to locate the entry referred to by the baseObject but was unable to search one or more non-local entries, the server may return one or more SearchResultReference messages, each containing a reference to another set of servers for continuing the operation. A server MUST NOT return any SearchResultReference messages if it has not located the baseObject and thus has not

Lightweight Directory Access Protocol Version 3

searched any entries; in this case it would return a SearchResultDone containing either a referral or noSuchObject result code (depending on the server's knowledge of the entry named in the baseObject).

If a server holds a copy or partial copy of the subordinate naming context (Section 5 of [\[Models\]](#)), it may use the search filter to determine whether or not to return a SearchResultReference response. Otherwise SearchResultReference responses are always returned when in scope.

The SearchResultReference is of the same data type as the Referral.

A URI for a server implementing LDAP and accessible via [\[TCP\]](#)/[\[IP\]](#) (v4 or v6) is written as an LDAP URL according to [\[LDAPURL\]](#).

In order to complete the Search, the client issues a new Search operation for each SearchResultReference that is returned. Note that the Abandon operation described in [Section 4.11](#) applies only to a particular operation sent at the LDAP message layer between a client and server. The client must abandon subsequent Search operations it wishes to individually.

Clients that follow search continuation references MUST ensure that they do not loop between servers. They MUST NOT repeatedly contact the same server for the same request with the same target entry name, scope and filter. Some clients use a counter that is incremented each time search result reference handling occurs for an operation, and these kinds of clients MUST be able to handle at least ten nested search result references between the root and a leaf entry.

SearchResultReference values which are LDAP URLs follow these rules:

- The <dn> part of the URL MUST be present, with the new target object name. The client MUST use this name when following the reference. UTF-8 encoded characters appearing in the string representation of a DN or search filter may not be legal for URLs (e.g. spaces) and MUST be escaped using the % method in [\[URI\]](#).
- Some servers (e.g. participating in distributed indexing) may provide a different filter in a URL of a SearchResultReference.
- If the <filter> part of the URL is present, the client MUST use this filter in its next request to progress this Search, and if it is not present the client MUST use the same filter as it used for that Search.
- If the originating search scope was singleLevel, the <scope> part of the URL will be "base".
- It is RECOMMENDED that the <scope> part be present to avoid ambiguity. In the absence of a <scope> part, the scope of the original Search request is assumed.

Lightweight Directory Access Protocol Version 3

- Other aspects of the new Search request may be the same as or different from the Search request which generated the SearchResultReference.
- The name of an unexplored subtree in a SearchResultReference need not be subordinate to the base object.

Other kinds of URIs may be returned. The syntax and semantics of such URIs is left to future specifications. Clients may ignore URIs that they do not support.

[4.5.3.1](#). Examples

For example, suppose the contacted server (hosta) holds the entry <DC=Example,DC=NET> and the entry <CN=Manager,DC=Example,DC=NET>. It knows that both LDAP servers (hostb) and (hostc) hold <OU=People,DC=Example,DC=NET> (one is the master and the other server a shadow), and that LDAP-capable server (hostd) holds the subtree <OU=Roles,DC=Example,DC=NET>. If a wholeSubtree Search of <DC=Example,DC=NET> is requested to the contacted server, it may return the following:

SearchResultEntry for DC=Example,DC=NET

```

SearchResultEntry for CN=Manager,DC=Example,DC=NET
SearchResultReference {
  ldap://hostb/OU=People,DC=Example,DC=NET??sub
  ldap://hostc/OU=People,DC=Example,DC=NET??sub }
SearchResultReference {
  ldap://hostd/OU=Roles,DC=Example,DC=NET??sub }
SearchResultDone (success)

```

Client implementors should note that when following a SearchResultReference, additional SearchResultReference may be generated. Continuing the example, if the client contacted the server (hostb) and issued the Search request for the subtree <OU=People,DC=Example,DC=NET>, the server might respond as follows:

```

SearchResultEntry for OU=People,DC=Example,DC=NET
SearchResultReference {
  ldap://hoste/OU=Managers,OU=People,DC=Example,DC=NET??sub }
SearchResultReference {
  ldap://hostf/OU=Consultants,OU=People,DC=Example,DC=NET??sub }
SearchResultDone (success)

```

Similarly, if a singleLevel Search of <DC=Example,DC=NET> is requested to the contacted server, it may return the following:

```

SearchResultEntry for CN=Manager,DC=Example,DC=NET
SearchResultReference {
  ldap://hostb/OU=People,DC=Example,DC=NET??base
  ldap://hostc/OU=People,DC=Example,DC=NET??base }
SearchResultReference {
  ldap://hostd/OU=Roles,DC=Example,DC=NET??base }

```

Lightweight Directory Access Protocol Version 3

```

SearchResultDone (success)

```

If the contacted server does not hold the base object for the Search, but has knowledge of its possible location, then it may return a referral to the client. In this case, if the client requests a subtree Search of <DC=Example,DC=ORG> to hosta, the server returns a SearchResultDone containing a referral.

```

SearchResultDone (referral) {
  ldap://hostg/DC=Example,DC=ORG??sub }

```

4.6. Modify Operation

The Modify operation allows a client to request that a modification of an entry be performed on its behalf by a server. The Modify Request is defined as follows:

```

ModifyRequest ::= [APPLICATION 6] SEQUENCE {
    object          LDAPDN,
    changes         SEQUENCE OF change SEQUENCE {
        operation   ENUMERATED {
            add      (0),
            delete   (1),
            replace   (2),
            ... },
        modification PartialAttribute } }

```

Fields of the Modify Request are:

- object: The value of this field contains the name of the entry to be modified. The server SHALL NOT perform any alias dereferencing in determining the object to be modified.
- changes: A list of modifications to be performed on the entry. The entire list of modifications MUST be performed in the order they are listed as a single atomic operation. While individual modifications may violate certain aspects of the directory schema (such as the object class definition and DIT content rule), the resulting entry after the entire list of modifications is performed MUST conform to the requirements of the directory model and controlling schema [[Models](#)].
- operation: Used to specify the type of modification being performed. Each operation type acts on the following modification. The values of this field have the following semantics respectively:

add: add values listed to the modification attribute, creating the attribute if necessary;

delete: delete values listed from the modification attribute. If no values are listed, or if all current values of the attribute are listed, the entire attribute is removed;

replace: replace all existing values of the modification attribute with the new values listed, creating the attribute if it did not already exist. A replace with no value will delete the entire attribute if it exists, and is ignored if the attribute does not exist.

- modification: A PartialAttribute (which may have an empty SET of vals) used to hold the attribute type or attribute type and values being modified.

Upon receipt of a Modify Request, the server attempts to perform the necessary modifications to the DIT and returns the result in a Modify Response, defined as follows:

ModifyResponse ::= [APPLICATION 7] LDAPResult

The server will return to the client a single Modify Response indicating either the successful completion of the DIT modification, or the reason that the modification failed. Due to the requirement for atomicity in applying the list of modifications in the Modify Request, the client may expect that no modifications of the DIT have been performed if the Modify Response received indicates any sort of error, and that all requested modifications have been performed if the Modify Response indicates successful completion of the Modify operation. Whether the modification was applied or not cannot be determined by the client if the Modify Response was not received (e.g. the LDAP session was terminated or the Modify operation was abandoned).

Servers MUST ensure that entries conform to user and system schema rules or other data model constraints. The Modify operation cannot be used to remove from an entry any of its distinguished values, i.e. those values which form the entry's relative distinguished name. An attempt to do so will result in the server returning the notAllowedOnRDN result code. The Modify DN operation described in [Section 4.9](#) is used to rename an entry.

For attribute types which specify no equality matching, the rules in Section 2.5.1 of [\[Models\]](#) are followed.

Note that due to the simplifications made in LDAP, there is not a direct mapping of the changes in an LDAP ModifyRequest onto the changes of a DAP ModifyEntry operation, and different implementations of LDAP-DAP gateways may use different means of representing the change. If successful, the final effect of the operations on the entry MUST be identical.

[4.7.](#) Add Operation

The Add operation allows a client to request the addition of an entry into the Directory. The Add Request is defined as follows:

AddRequest ::= [APPLICATION 8] SEQUENCE {
 entry LDAPDN,
 attributes AttributeList }

AttributeList ::= SEQUENCE OF attribute Attribute

Fields of the Add Request are:

- entry: the name of the entry to be added. The server SHALL NOT dereference any aliases in locating the entry to be added.
- attributes: the list of attributes that, along with those from the RDN, make up the content of the entry being added. Clients MAY or MAY NOT include the RDN attribute(s) in this list. Clients MUST NOT supply NO-USER-MODIFICATION attributes such as the createTimeStamp or creatorsName attributes, since the server maintains these automatically.

Servers MUST ensure that entries conform to user and system schema rules or other data model constraints. For attribute types which specify no equality matching, the rules in Section 2.5.1 of [\[Models\]](#) are followed (this applies to the naming attribute in addition to any multi-valued attributes being added).

The entry named in the entry field of the AddRequest MUST NOT exist for the AddRequest to succeed. The immediate superior (parent) of an object or alias entry to be added MUST exist. For example, if the client attempted to add <CN=JS,DC=Example,DC=NET>, the <DC=Example,DC=NET> entry did not exist, and the <DC=NET> entry did exist, then the server would return the noSuchObject result code with the matchedDN field containing <DC=NET>.

Upon receipt of an Add Request, a server will attempt to add the requested entry. The result of the Add attempt will be returned to the client in the Add Response, defined as follows:

AddResponse ::= [APPLICATION 9] LDAPResult

A response of success indicates that the new entry has been added to the Directory.

4.8. Delete Operation

The Delete operation allows a client to request the removal of an entry from the Directory. The Delete Request is defined as follows:

DelRequest ::= [APPLICATION 10] LDAPDN

The Delete Request consists of the name of the entry to be deleted. The server SHALL NOT dereference aliases while resolving the name of the target entry to be removed.

Lightweight Directory Access Protocol Version 3

Only leaf entries (those with no subordinate entries) can be deleted with this operation.

Upon receipt of a Delete Request, a server will attempt to perform the entry removal requested and return the result in the Delete Response defined as follows:

DelResponse ::= [APPLICATION 11] LDAPResult

4.9. Modify DN Operation

The Modify DN operation allows a client to change the Relative Distinguished Name (RDN) of an entry in the Directory, and/or to move a subtree of entries to a new location in the Directory. The Modify DN Request is defined as follows:

```
ModifyDNRequest ::= [APPLICATION 12] SEQUENCE {  
    entry          LDAPDN,  
    newrdn         RelativeLDAPDN,  
    deleteoldrdn  BOOLEAN,  
    newSuperior    [0] LDAPDN OPTIONAL }
```

Fields of the Modify DN Request are:

- entry: the name of the entry to be changed. This entry may or may not have subordinate entries.
- newrdn: the new RDN of the entry. The value of the old RDN is supplied when moving the entry to a new superior without changing its RDN. Attribute values of the new RDN not matching any attribute value of the entry are added to the entry and an appropriate error is returned if this fails.
- deleteoldrdn: a boolean field that controls whether the old RDN attribute values are to be retained as attributes of the entry, or deleted from the entry.
- newSuperior: if present, this is the name of an existing object entry which becomes the immediate superior (parent) of the existing entry.

The server SHALL NOT dereference any aliases in locating the objects named in entry or newSuperior.

Upon receipt of a ModifyDNRequest, a server will attempt to perform the name change and return the result in the Modify DN Response, defined as follows:

ModifyDNResponse ::= [APPLICATION 13] LDAPResult

For example, if the entry named in the entry field was <cn=John Smith,c=US>, the newrdn field was <cn=John Cougar Smith>, and the newSuperior field was absent, then this operation would attempt to

Lightweight Directory Access Protocol Version 3

rename the entry to be <cn=John Cougar Smith,c=US>. If there was already an entry with that name, the operation would fail with the entryAlreadyExists result code.

Servers MUST ensure that entries conform to user and system schema rules or other data model constraints. For attribute types which specify no equality matching, the rules in Section 2.5.1 of [[Models](#)] are followed (this pertains to newrdn and deleteolddn).

The object named in newSuperior MUST exist. For example, if the client attempted to add <CN=JS,DC=Example,DC=NET>, the <DC=Example,DC=NET> entry did not exist, and the <DC=NET> entry did exist, then the server would return the noSuchObject result code with the matchedDN field containing <DC=NET>.

If the deleteolddn field is TRUE, the attribute values forming the old RDN but not the new RDN are deleted from the entry. If the deleteolddn field is FALSE, the attribute values forming the old RDN will be retained as non-distinguished attribute values of the entry.

Note that X.500 restricts the ModifyDN operation to only affect entries that are contained within a single server. If the LDAP server is mapped onto DAP, then this restriction will apply, and the affectsMultipleDSAs result code will be returned if this error occurred. In general, clients MUST NOT expect to be able to perform arbitrary movements of entries and subtrees between servers or between naming contexts.

[4.10. Compare Operation](#)

The Compare operation allows a client to compare an assertion value with the values of a particular attribute in a particular entry in the Directory. The Compare Request is defined as follows:

```
CompareRequest ::= [APPLICATION 14] SEQUENCE {  
    entry          LDAPDN,  
    ava            AttributeValueAssertion }
```

Fields of the Compare Request are:

- entry: the name of the entry to be compared. The server SHALL NOT dereference any aliases in locating the entry to be compared.
- ava: holds the attribute value assertion to be compared.

Upon receipt of a Compare Request, a server will attempt to perform the requested comparison and return the result in the Compare Response, defined as follows:

CompareResponse ::= [APPLICATION 15] LDAPResult

The resultCode is set to compareTrue, compareFalse, or an appropriate error. compareTrue indicates that the assertion value in the ava

Lightweight Directory Access Protocol Version 3

field matches a value of the attribute or subtype according to the attribute's EQUALITY matching rule. compareFalse indicates that the assertion value in the ava field and the values of the attribute or subtype did not match. Other result codes indicate either that the result of the comparison was Undefined ([Section 4.5.1](#)), or that some error occurred.

Note that some directory systems may establish access controls which permit the values of certain attributes (such as userPassword) to be compared but not interrogated by other means.

4.11. Abandon Operation

The function of the Abandon operation is to allow a client to request that the server abandon an uncompleted operation. The Abandon Request is defined as follows:

AbandonRequest ::= [APPLICATION 16] MessageID

The MessageID is that of an operation which was requested earlier at this LDAP message layer. The Abandon request itself has its own MessageID. This is distinct from the MessageID of the earlier operation being abandoned.

There is no response defined in the Abandon operation. Upon receipt of an AbandonRequest, the server MAY abandon the operation identified by the MessageID. Since the client cannot tell the difference between a successfully abandoned operation and an uncompleted operation, the application of the Abandon operation is limited to uses where the client does not require an indication of its outcome.

Abandon, Bind, Unbind, and StartTLS operations cannot be abandoned.

In the event that a server receives an Abandon Request on a Search operation in the midst of transmitting responses to the Search, that server MUST cease transmitting entry responses to the abandoned request immediately, and MUST NOT send the SearchResponseDone. Of course, the server MUST ensure that only properly encoded LDAPMessage PDUs are transmitted.

The ability to abandon other (particularly update) operations is at the discretion of the server.

Clients should not send Abandon requests for the same operation multiple times, and MUST also be prepared to receive results from operations it has abandoned (since these may have been in transit when the Abandon was requested, or are not able to be abandoned).

Servers MUST discard Abandon requests for message IDs they do not recognize, for operations which cannot be abandoned, and for operations which have already been abandoned.

4.12. Extended Operation

The Extended operation allows additional operations to be defined for services not already available in the protocol. For example, to Add operations to install transport layer security (see [Section 4.14](#)).

The Extended operation allows clients to make requests and receive responses with predefined syntaxes and semantics. These may be defined in RFCs or be private to particular implementations.

Each Extended operation consists of an Extended request and an Extended response.

```
ExtendedRequest ::= [APPLICATION 23] SEQUENCE {  
    requestName      [0] LDAPOID,  
    requestValue     [1] OCTET STRING OPTIONAL }
```

The requestName is a dotted-decimal representation of the unique OBJECT IDENTIFIER corresponding to the request. The requestValue is information in a form defined by that request, encapsulated inside an OCTET STRING.

The server will respond to this with an LDAPMessage containing an ExtendedResponse.

```
ExtendedResponse ::= [APPLICATION 24] SEQUENCE {  
    COMPONENTS OF LDAPResult,
```

```
responseName    [10] LDAPOID OPTIONAL,  
responseValue   [11] OCTET STRING OPTIONAL }
```

The responseName is typically not required to be present as the syntax and semantics of the response (including the format of the responseValue) is implicitly known and associated with the request by the messageID.

If the Extended operation associated with the requestName is not supported by the server, the server MUST NOT provide a responseName nor a responseValue and MUST return with resultCode set to protocolError.

The requestValue and responseValue fields contain any information associated with the operation. The format of these fields is defined by the specification of the Extended operation. Implementations MUST be prepared to handle arbitrary contents of these fields, including zero bytes. Values that are defined in terms of ASN.1 and BER encoded according to [Section 5.1](#), also follow the extensibility rules in [Section 4](#).

Servers list the requestName of Extended Requests they recognize in the 'supportedExtension' attribute in the root DSE (Section 5.1 of [\[Models\]](#)).

Extended operations may be specified in other documents. The specification of an Extended operation consists of:

Sermersheim Internet-Draft - Expires May 2005 Page 34

Lightweight Directory Access Protocol Version 3

- the OBJECT IDENTIFIER assigned to the requestName,
- the OBJECT IDENTIFIER (if any) assigned to the responseName (note that the same OBJECT IDENTIFIER may be used for both the requestName and responseName),
- the format of the contents of the requestValue and responseValue (if any), and
- the semantics of the operation.

[4.13](#). IntermediateResponse Message

While the Search operation provides a mechanism to return multiple response messages for a single Search request, other operations, by nature, do not provide for multiple response messages.

The IntermediateResponse message provides a general mechanism for

defining single-request/multiple-response operations in LDAP. This message is intended to be used in conjunction with the Extended operation to define new single-request/multiple-response operations or in conjunction with a control when extending existing LDAP operations in a way that requires them to return Intermediate response information.

It is intended that the definitions and descriptions of Extended operations and controls that make use of the IntermediateResponse message will define the circumstances when an IntermediateResponse message can be sent by a server and the associated meaning of an IntermediateResponse message sent in a particular circumstance.

```
IntermediateResponse ::= [APPLICATION 25] SEQUENCE {  
    responseName      [0] LDAPOID OPTIONAL,  
    responseValue     [1] OCTET STRING OPTIONAL }
```

IntermediateResponse messages SHALL NOT be returned to the client unless the client issues a request that specifically solicits their return. This document defines two forms of solicitation: Extended operation and request control. IntermediateResponse messages are specified in documents describing the manner in which they are solicited (i.e. in the Extended operation or request control specification that uses them). These specifications include:

- the OBJECT IDENTIFIER (if any) assigned to the responseName,
- the format of the contents of the responseValue (if any), and
- the semantics associated with the IntermediateResponse message.

Extensions that allow the return of multiple types of IntermediateResponse messages SHALL identify those types using unique responseName values (note that one of these may specify no value).

Sermersheim Internet-Draft - Expires May 2005 Page 35

Lightweight Directory Access Protocol Version 3

Sections [4.13.1](#) and [4.13.2](#) describe additional requirements on the inclusion of responseName and responseValue in IntermediateResponse messages.

[4.13.1](#). Usage with LDAP ExtendedRequest and ExtendedResponse

A single-request/multiple-response operation may be defined using a single ExtendedRequest message to solicit zero or more IntermediateResponse messages of one or more kinds followed by an ExtendedResponse message.

4.13.2. Usage with LDAP Request Controls

A control's semantics may include the return of zero or more IntermediateResponse messages prior to returning the final result code for the operation. One or more kinds of IntermediateResponse messages may be sent in response to a request control.

All IntermediateResponse messages associated with request controls SHALL include a responseName. This requirement ensures that the client can correctly identify the source of IntermediateResponse messages when:

- two or more controls using IntermediateResponse messages are included in a request for any LDAP operation or
- one or more controls using IntermediateResponse messages are included in a request with an LDAP Extended operation that uses IntermediateResponse messages.

4.14. StartTLS Operation

The Start Transport Layer Security (StartTLS) operation's purpose is to initiate installation of a TLS layer. The StartTLS operation is defined using the Extended operation mechanism described in [Section 4.12](#).

4.14.1. StartTLS Request

A client requests TLS establishment by transmitting a StartTLS request PDU to the server. The StartTLS request is defined in terms of an ExtendedRequest. The requestName is "1.3.6.1.4.1.1466.20037", and the requestValue field is always absent.

The client MUST NOT send any PDUs at this LDAP message layer following this request until it receives a StartTLS Extended response and, in the case of a successful response, completes TLS negotiations.

Detected sequencing problems (particularly those detailed in [Section 3.1.1](#) of [[AuthMeth](#)]) result in the resultCode being set to operationsError.

If the server does not support TLS (whether by design or by current configuration), it returns with the resultCode set to protocolError

as described in [Section 4.12](#).

[4.14.2. StartTLS Response](#)

When a StartTLS request is made, servers supporting the operation MUST return a StartTLS response PDU to the requestor. The responseName, if present, is also "1.3.6.1.4.1.1466.20037". The responseValue is absent.

If the server is willing and able to negotiate TLS, it returns with the resultCode set to success. Refer to Section 4 of [\[AuthMeth\]](#) for details.

If the server is otherwise unwilling or unable to perform this operation, the server is to return an appropriate result code indicating the nature of the problem. For example, if the TLS subsystem is not presently available, the server may indicate so by returning with the resultCode set to unavailable.

[4.14.3. Removal of the TLS Layer](#)

Two forms of TLS layer removal -- graceful and abrupt -- are provided. These do not involve LDAP PDUs, but are preformed at the underlying layers.

If the transport connection is closed, uncompleted operations are handled as specified in [Section 5.1](#).

[4.14.3.1. Graceful Removal](#)

Either the client or server MAY remove the TLS layer and leave the LDAP message layer intact by sending and receiving a TLS closure alert.

The initiating protocol peer sends the TLS closure alert. If it wishes to leave the LDAP message layer intact, it then MUST cease to send further PDUs and MUST ignore any received LDAP PDUs until it receives a TLS closure alert from the other peer.

Once the initiating protocol peer receives a TLS closure alert from the other peer it MAY send and receive LDAP PDUs.

When a protocol peer receives the initial TLS closure alert, it may choose to allow the LDAP message layer to remain intact. In this

case, it MUST immediately transmit a TLS closure alert. Following this, it MAY send and receive LDAP PDUs.

Protocol peers MAY close the transport connection after sending or receiving a TLS closure alert.

After the TLS layer has been removed, the server MUST NOT send responses to any request message received before the TLS closure alert. Thus, clients wishing to receive responses to messages sent while the TLS layer is intact MUST wait for those message responses before sending the TLS closure alert.

4.14.3.2. Abrupt Removal

Either the client or server MAY abruptly remove the TLS layer by closing the transport connection. In this circumstance, a server MAY send the client a Notice of Disconnection before closing the transport connection.

5. Protocol Encoding, Connection, and Transfer

This protocol is designed to run over connection-oriented, reliable transports, where the data stream is divided into octets (8-bit units), with each octet and each bit being significant.

One underlying service, LDAP over TCP, is defined in [Section 5.2](#). This service is generally applicable to applications providing or consuming X.500-based directory services on the Internet. This specification was generally written with the TCP mapping in mind. Specifications detailing other mappings may encounter various obstacles.

Implementations of LDAP over TCP MUST implement the mapping as described in [Section 5.2](#).

This table illustrates the relationship between the different layers involved in an exchange between two protocol peers:

	+-----+	
	LDAP message layer	
	+-----+	> LDAP PDUs
	+-----+	< data
	SASL layer	
	+-----+	> SASL-protected data
	+-----+	< data
	TLS layer	
Application	+-----+	> TLS-protected data
	+-----+	< data
Transport	transport connection	

Lightweight Directory Access Protocol Version 3

+-----+

5.1. Protocol Encoding

The protocol elements of LDAP SHALL be encoded for exchange using the Basic Encoding Rules [BER] of [ASN.1] with the following restrictions:

- Only the definite form of length encoding is used.
- OCTET STRING values are encoded in the primitive form only.
- If the value of a BOOLEAN type is true, the encoding of the value octet is set to hex "FF".
- If a value of a type is its default value, it is absent. Only some BOOLEAN and INTEGER types have default values in this protocol definition.

These restrictions are meant to ease the overhead of encoding and decoding certain elements in BER.

These restrictions do not apply to ASN.1 types encapsulated inside of OCTET STRING values, such as attribute values, unless otherwise stated.

5.2. Transmission Control Protocol (TCP)

The encoded LDAPMessage PDUs are mapped directly onto the [TCP] bytestream using the BER-based encoding described in [Section 5.1](#). It is recommended that server implementations running over the TCP provide a protocol listener on the Internet Assigned Numbers Authority (IANA)-assigned LDAP port, 389 [PortReg]. Servers may instead provide a listener on a different port number. Clients MUST support contacting servers on any valid TCP port.

6. Security Considerations

This version of the protocol provides facilities for simple authentication using a cleartext password, as well as any [SASL] mechanism. Installing SASL and/or TLS layers can provide integrity and other data security services.

It is also permitted that the server can return its credentials to the client, if it chooses to do so.

Use of cleartext password is strongly discouraged where the underlying transport service cannot guarantee confidentiality and may result in disclosure of the password to unauthorized parties.

Lightweight Directory Access Protocol Version 3

Servers are encouraged to prevent directory modifications by clients that have authenticated anonymously [[AuthMeth](#)].

Security considerations for authentication methods, SASL mechanisms, and TLS are described in [[AuthMeth](#)].

It should be noted that SASL authentication exchanges do not provide data confidentiality nor integrity protection for the version or name fields of the BindRequest nor the resultCode, diagnosticMessage, or referral fields of the BindResponse nor of any information contained in controls attached to Bind requests or responses. Thus information contained in these fields SHOULD NOT be relied on unless otherwise protected (such as by establishing protections at the transport layer).

Server implementors should plan for the possibility of (protocol or external) events which alter the information used to establish security factors (e.g., credentials, authorization identities, access controls) during the course of the LDAP session, and even during the performance of a particular operation, and should take steps to avoid insecure side effects of these changes. The ways in which these issues are addressed are application and/or implementation specific.

Implementations which cache attributes and entries obtained via LDAP MUST ensure that access controls are maintained if that information is to be provided to multiple clients, since servers may have access control policies which prevent the return of entries or attributes in Search results except to particular authenticated clients. For example, caches could serve result information only to the client whose request caused it to be in the cache.

Servers may return referrals or Search result references which redirect clients to peer servers. It is possible for a rogue application to inject such referrals into the data stream in an attempt to redirect a client to a rogue server. Clients are advised to be aware of this, and possibly reject referrals when confidentiality measures are not in place. Clients are advised to reject referrals from the StartTLS operation.

The matchedDN and diagnosticMessage fields, as well as some resultCode values (e.g., attributeOrValueExists and

entryAlreadyExists), could disclose the presence or absence of specific data in the directory which is subject to access and other administrative controls. Server implementations should restrict access to protected information equally under both normal and error conditions.

Protocol peers MUST be prepared to handle invalid and arbitrary length protocol encodings. Invalid protocol encodings include: BER encoding exceptions, format string and UTF-8 encoding exceptions, overflow exceptions, integer value exceptions, and binary mode on/off flag exceptions. The LDAPv3 PROTOs [[PROTOs-LDAP](#)] test suite provides excellent examples of these exceptions and test cases used to discover flaws.

10. IANA Considerations

It is requested that the Internet Assigned Numbers Authority (IANA) update the LDAP result code registry to indicate that this document provides the definitive technical specification for result codes 0-36, 48-54, 64-70, 80-90.

It is requested that the IANA update the LDAP Protocol Mechanism registry to indicate that this document and [[AuthMeth](#)] provides the definitive technical specification for the StartTLS (1.3.6.1.4.1.1466.20037) Extended operation.

It is requested that the IANA update the occurrence of "RFC XXXX" in [Appendix B](#) with this RFC number at publication.

Appendix A - LDAP Result Codes

This normative appendix details additional considerations regarding LDAP result codes and provides a brief, general description of each LDAP result code enumerated in [Section 4.1.9](#).

Additional result codes MAY be defined for use with extensions [[LDAPIANA](#)]. Client implementations SHALL treat any result code which they do not recognize as an unknown error condition.

Servers may substitute some result codes due to access controls which prevent their disclosure.

[A.1](#) Non-Error Result Codes

These result codes (called "non-error" result codes) do not indicate an error condition:

- success (0),
- compareFalse (5),
- compareTrue (6),
- referral (10), and
- saslBindInProgress (14).

The success, compareTrue, and compareFalse result codes indicate successful completion (and, hence, are referred to as "successful" result codes).

The referral and saslBindInProgress result codes indicate the client needs to take additional action to complete the operation.

[A.2](#) Result Codes

Existing LDAP result codes are described as follows:

success (0)

Indicates the successful completion of an operation. Note: this code is not used with the Compare operation. See compareFalse (5) and compareTrue (6).

operationsError (1)

Indicates that the operation is not properly sequenced with relation to other operations (of same or different type).

For example, this code is returned if the client attempts to StartTLS [[TLS](#)] while there are other uncompleted operations or if a TLS layer was already installed.

protocolError (2)

Indicates the server received data which is not well-formed.

For Bind operation only, this code is also used to indicate that the server does not support the requested protocol version.

For Extended operations only, this code is also used to indicate that the server does not support (by design or configuration) the Extended operation associated with the

requestName.

For request operations specifying multiple controls, this may be used to indicate that the server cannot ignore the order of the controls as specified, or that the combination of the specified controls is invalid or unspecified.

timeLimitExceeded (3)

Indicates that the time limit specified by the client was exceeded before the operation could be completed.

sizeLimitExceeded (4)

Indicates that the size limit specified by the client was exceeded before the operation could be completed.

compareFalse (5)

Indicates that the Compare operation has successfully completed and the assertion has evaluated to FALSE or Undefined.

compareTrue (6)

Indicates that the Compare operation has successfully completed and the assertion has evaluated to TRUE.

authMethodNotSupported (7)

Indicates that the authentication method or mechanism is not supported.

strongAuthRequired (8)

Indicates the server requires the client to authenticate using a strong(er) mechanism.

When used with the Notice of Disconnection operation, this code indicates that the server has detected that an established security association between the client and server has unexpectedly failed or been compromised.

referral (10)

Indicates that a referral needs to be chased to complete the operation (see [Section 4.1.10](#)).

adminLimitExceeded (11)

Indicates that an administrative limit has been exceeded.

unavailableCriticalExtension (12)

Indicates a critical control is unrecognized (see [Section 4.1.11](#)).

confidentialityRequired (13)

Indicates that data confidentiality protections are required.

saslBindInProgress (14)

Indicates the server requires the client to send a new bind request, with the same SASL mechanism, to continue the authentication process (see [Section 4.2](#)).

noSuchAttribute (16)

Indicates that the named entry does not contain the specified attribute or attribute value.

undefinedAttributeType (17)

Indicates that a request field contains an unrecognized attribute description.

inappropriateMatching (18)

Indicates that an attempt was made (e.g. in an assertion) to use a matching rule not defined for the attribute type concerned.

constraintViolation (19)

Indicates that the client supplied an attribute value which does not conform to the constraints placed upon it by the data model.

For example, this code is returned when multiple values are supplied to an attribute which has a SINGLE-VALUE constraint.

attributeOrValueExists (20)

Indicates that the client supplied an attribute or value to be added to an entry, but the attribute or value already exists.

invalidAttributeSyntax (21)

Indicates that a purported attribute value does not conform to the syntax of the attribute.

noSuchObject (32)

Indicates that the object does not exist in the DIT.

aliasProblem (33)

Indicates that an alias problem has occurred. For example, the code may be used to indicate an alias has been dereferenced which names no object.

invalidDNSyntax (34)

Indicates that an LDAPDN or RelativeLDAPDN field (e.g. search base, target entry, ModifyDN newrdn, etc.) of a request does not conform to the required syntax or contains attribute values which do not conform to the syntax of the attribute's

type.

Lightweight Directory Access Protocol Version 3

aliasDereferencingProblem (36)

Indicates that a problem occurred while dereferencing an alias. Typically an alias was encountered in a situation where it was not allowed or where access was denied.

inappropriateAuthentication (48)

Indicates the server requires the client which had attempted to bind anonymously or without supplying credentials to provide some form of credentials.

invalidCredentials (49)

Indicates that the provided credentials (e.g. the user's name and password) are invalid.

insufficientAccessRights (50)

Indicates that the client does not have sufficient access rights to perform the operation.

busy (51)

Indicates that the server is too busy to service the operation.

unavailable (52)

Indicates that the server is shutting down or a subsystem necessary to complete the operation is offline.

unwillingToPerform (53)

Indicates that the server is unwilling to perform the operation.

loopDetect (54)

Indicates that the server has detected an internal loop (e.g. while dereferencing aliases or chaining an operation).

namingViolation (64)

Indicates that the entry's name violates naming restrictions.

objectClassViolation (65)

Indicates that the entry violates object class restrictions.

notAllowedOnNonLeaf (66)

Indicates that the operation is inappropriately acting upon a non-leaf entry.

notAllowedOnRDN (67)

Indicates that the operation is inappropriately attempting to remove a value which forms the entry's relative distinguished name.

`entryAlreadyExists` (68)

Indicates that the request cannot be fulfilled (added, moved, or renamed) as the target entry already exists.

`objectClassModsProhibited` (69)

Lightweight Directory Access Protocol Version 3

Indicates that an attempt to modify the object class(es) of an entry's 'objectClass' attribute is prohibited.

For example, this code is returned when a client attempts to modify the structural object class of an entry.

`affectsMultipleDSAs` (71)

Indicates that the operation cannot be performed as it would affect multiple servers (DSAs).

`other` (80)

Indicates the server has encountered an internal error.

Lightweight Directory Access Protocol Version 3

Lightweight Directory Access Protocol Version 3

Appendix C - Changes

This appendix is non-normative.

This appendix summarizes substantive changes made to [RFC 2251](#), [RFC 2830](#), and [RFC 3771](#).

C.1 Changes made to [RFC 2251](#):

This section summarizes the substantive changes made to Sections [1](#), [2](#), [3.1](#), and [4](#) through the remainder of [RFC 2251](#). Readers should consult [[Models](#)] and [[AuthMeth](#)] for summaries of changes to other sections.

C.1.1 [Section 1](#) (Status of this Memo)

- Removed IESG note. Post publication of [RFC 2251](#), mandatory LDAP authentication mechanisms have been standardized which are sufficient to remove this note. See [[AuthMeth](#)] for authentication mechanisms.

C.1.2 [Section 3.1](#) (Protocol Model) and others

- Removed notes giving history between LDAP v1, v2 and v3. Instead, added sufficient language so that this document can stand on its own.

C.1.3 [Section 4](#) (Elements of Protocol)

- Clarified where the extensibility features of ASN.1 apply to the protocol. This change affected various ASN.1 types by the inclusion of ellipses (...) to certain elements.
- Removed the requirement that servers which implement version 3 or later MUST provide the 'supportedLDAPVersion' attribute. This statement provided no interoperability advantages.

C.1.4 [Section 4.1.1](#) (Message Envelope)

- There was a mandatory requirement for the server to return a Notice of Disconnection and drop the transport connection when a PDU is malformed in a certain way. This has been updated such that the server SHOULD return the Notice of Disconnection, and MUST

drop the transport connection.

C.1.5 Section 4.1.1.1 (Message ID)

- Required that the messageID of requests MUST be non-zero as the zero is reserved for Notice of Disconnection.

Sermersheim

Internet-Draft - Expires May 2005

Page 55

Lightweight Directory Access Protocol Version 3

- Specified when it is and isn't appropriate to return an already used message id. [RFC 2251](#) accidentally imposed synchronous server behavior in its wording of this.

C.1.6 Section 4.1.2 (String Types)

- Stated that LDAPOID is constrained to <numericoid> from [[Models](#)].

C.1.7 Section 4.1.5.1 (Binary Option) and others

- Removed the Binary Option from the specification. There are numerous interoperability problems associated with this method of alternate attribute type encoding. Work to specify a suitable replacement is ongoing.

C.1.8 Section 4.1.8 (Attribute)

- Combined the definitions of PartialAttribute and Attribute here, and defined Attribute in terms of PartialAttribute.

C.1.9 Section 4.1.10 (Result Message)

- Renamed "errorMessage" to "diagnosticMessage" as it is allowed to be sent for non-error results.
- Moved some language into [Appendix A](#), and refer the reader there.
- Allowed matchedDN to be present for other result codes than those listed in [RFC 2251](#).

C.1.10 Section 4.1.11 (Referral)

- Defined referrals in terms of URIs rather than URLs.
- Removed the requirement that all referral URIs MUST be equally capable of progressing the operation. The statement was ambiguous and provided no instructions on how to carry it out.
- Added the requirement that clients MUST NOT loop between servers.
- Clarified the instructions for using LDAPURLs in referrals, and in

doing so added a recommendation that the scope part be present.

- Removed imperatives which required clients to use URLs in specific ways to progress an operation. These did nothing for interoperability.

C.1.11 Section 4.1.12 (Controls)

- Specified how control values defined in terms of ASN.1 are to be encoded.
- Noted that the criticality field is only applied to request messages (except UnbindRequest), and must be ignored when present on response messages and UnbindRequest.

Sermersheim

Internet-Draft - Expires May 2005

Page 56

Lightweight Directory Access Protocol Version 3

- Added language regarding combinations of controls and the ordering of controls on a message.
- Specified that when the semantics of the combination of controls is undefined or unknown, it results in a protocolError.
- Changed "The server MUST be prepared" to "Implementations MUST be prepared" in the eighth paragraph to reflect that both client and server implementations must be able to handle this (as both parse controls).

C.1.12 Section 4.2 (Bind Operation)

- Mandated that servers return protocolError when the version is not supported.
- Disambiguated behavior when the simple authentication is used, the name is empty and the password is non-empty.
- Required servers to not dereference aliases for Bind. This was added for consistency with other operations and to help ensure data consistency.
- Required that textual passwords be transferred as UTF-8 encoded Unicode, and added recommendations on string preparation. This was to help ensure interoperability of passwords being sent from different clients.

C.1.13 Section 4.2.1 (Sequencing of the Bind Request)

- This section was largely reorganized for readability and language was added to clarify the authentication state of failed and abandoned Bind operations.
- Removed: "If a SASL transfer encryption or integrity mechanism has been negotiated, that mechanism does not support the changing of credentials from one identity to another, then the client MUST instead establish a new connection."

If there are dependencies between multiple negotiations of a particular SASL mechanism, the technical specification for that SASL mechanism details how applications are to deal with them. LDAP should not require any special handling.

- Dropped MUST imperative in paragraph 3 to align with [Keywords].
- Mandated that clients not send non-Bind operations while a Bind is in progress, and suggested that servers not process them if they are received. This is needed to ensure proper sequencing of the Bind in relationship to other operations.

[C.1.14](#) [Section 4.2.3](#) (Bind Response)

- Moved most error-related text to [Appendix A](#), and added text regarding certain errors used in conjunction with the Bind operation.
- Prohibited the server from specifying serverSaslCreds when not appropriate.

[C.1.15](#) [Section 4.3](#) (Unbind Operation)

- Specified that both peers are to cease transmission and close the transport connection for the Unbind operation.

[C.1.16](#) [Section 4.4](#) (Unsolicited Notification)

- Added instructions for future specifications of Unsolicited Notifications.

[C.1.17](#) [Section 4.5.1](#) (Search Request)

- SearchRequest attributes is now defined as an AttributeSelection type rather than AttributeDescriptionList, and an ABNF is provided.
- SearchRequest attributes may contain duplicate attribute descriptions. This was previously prohibited. Now servers are instructed to ignore subsequent names when they are duplicated. This was relaxed in order to allow different short names and also OIDs to be requested for an attribute.
- The Filter choice SubstringFilter substrings type is now defined with a lower bound of 1.
- The SubstringFilter substrings 'initial', 'any', and 'final' types are now AssertionValue rather than LDAPString. Also, added imperatives stating that 'initial' (if present) must be listed

- first, and 'final' (if present) must be listed last.
- Disambiguated the semantics of the derefAliases choices. There was question as to whether derefInSearching applied to the base object in a wholeSubtree Search.
- Added instructions for equalityMatch, substrings, greaterOrEqual, lessOrEqual, and approxMatch.

[C.1.18 Section 4.5.2](#) (Search Result)

- Recommended that servers not use attribute short names when it knows they are ambiguous or may cause interoperability problems.
- Removed all mention of ExtendedResponse due to lack of implementation.

[C.1.19 Section 4.5.3](#) (Continuation References in the Search Result)

- Made changes similar to those made to [Section 4.1.11](#).

[C.1.20 Section 4.5.3.1](#) (Example)

- Fixed examples to adhere to changes made to [Section 4.5.3](#).

[C.1.21 Section 4.6](#) (Modify Operation)

Sermersheim Internet-Draft - Expires May 2005 Page 58

Lightweight Directory Access Protocol Version 3

- Replaced AttributeTypeAndValues with Attribute as they are equivalent.
- Specified the types of modification changes which might temporarily violate schema. Some readers were under the impression that any temporary schema violation was allowed.

[C.1.22 Section 4.7](#) (Add Operation)

- Aligned Add operation with X.511 in that the attributes of the RDN are used in conjunction with the listed attributes to create the entry. Previously, Add required that the distinguished values be present in the listed attributes.
- Removed requirement that the objectclass attribute MUST be specified as some DSE types do not require this attribute. Instead, generic wording was added, requiring the added entry to adhere to the data model.
- Removed recommendation regarding placement of objects. This is covered in the data model document.

C.1.23 Section 4.9 (Modify DN Operation)

- Required servers to not dereference aliases for Modify DN. This was added for consistency with other operations and to help ensure data consistency.
- Allow Modify DN to fail when moving between naming contexts.
- Specified what happens when the attributes of the newrdn are not present on the entry.

C.1.24 Section 4.10 (Compare Operation)

- Specified that compareFalse means that the Compare took place and the result is false. There was confusion which lead people to believe that an Undefined match resulted in compareFalse.
- Required servers to not dereference aliases for Compare. This was added for consistency with other operations and to help ensure data consistency.

C.1.25 Section 4.11 (Abandon Operation)

- Explained that since Abandon returns no response, clients should not use it if they need to know the outcome.
- Specified that Abandon and Unbind cannot be abandoned.

C.1.26 Section 4.12 (Extended Operation)

- Specified how values of Extended operations defined in terms of ASN.1 are to be encoded.

Lightweight Directory Access Protocol Version 3

- Added instructions on what Extended operation specifications consist of.
- Added a recommendation that servers advertise supported Extended operations.

C.1.27 Section 5.2 (Transfer Protocols)

- Moved referral-specific instructions into referral-related sections.

C.1.28 Section 7 (Security Considerations)

- Reworded notes regarding SASL not protecting certain aspects of the LDAP Bind PDUs.
- Noted that Servers are encouraged to prevent directory modifications by clients that have authenticated anonymously [[AuthMeth](#)].
- Added a note regarding the scenario where an identity is changed (deleted, privileges or credentials modified, etc.).
- Warned against following referrals that may have been injected in the data stream.
- Noted that servers should protect information equally, whether in an error condition or not, and mentioned specifically; matchedDN, diagnosticMessage, and resultCodes.
- Added a note regarding malformed and long encodings.

[C.1.29 Appendix A](#) (Complete ASN.1 Definition)

- Added "EXTENSIBILITY IMPLIED" to ASN.1 definition.
- Removed AttributeType. It is not used.

[C.2](#) Changes made to [RFC 2830](#):

This section summarizes the substantive changes made to Sections of [RFC 2830](#). Readers should consult [[AuthMeth](#)] for summaries of changes to other sections.

[C.2.1 Section 2.3](#) (Response other than "success")

- Removed wording indicating that referrals can be returned from StartTLS.
- Removed requirement that only a narrow set of result codes can be returned. Some result codes are required in certain scenarios, but any other may be returned if appropriate.

[C.2.1 Section 4](#) (Closing a TLS Connection)

- Reworded most of this section and added the requirement that after the TLS connection has been closed, the server MUST NOT send responses to any request message received before the TLS closure.

[C.3](#) Changes made to [RFC 3771](#):

- Rewrote to fit into this document. In general, semantics were preserved. Supporting and background language seen as redundant due to its presence in this document was omitted.
- Specified that Intermediate responses to a request may be of different types, and one of the response types may be specified to have no response value.

Intellectual Property Statement

The IETF takes no position regarding the validity or scope of any Intellectual Property Rights or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; nor does it represent that it has made any independent effort to identify any such rights. Information on the procedures with respect to rights in RFC documents can be found in [BCP 78](#) and [BCP 79](#).

Copies of IPR disclosures made to the IETF Secretariat and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF on-line IPR repository at [<http://www.ietf.org/ipr>](http://www.ietf.org/ipr).

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights that may cover technology that may be required to implement this standard. Please address the information to the IETF at ietf-ipr@ietf.org.
