          Network-Hexagons: H3-LISP GeoState & Mobility Network
                     draft-ietf-lisp-nexagon-15

Abstract

   This document specifies the use of H3 and LISP for Geolocation
   services, utilizing geospatial data to mobility use-cases:
   fresh HDMaps, Intelligent Driving, Cruise and Parking assists.
   This is achieved by:
   - EID addressable geospatial abstraction of road-segments.
   - EID Interface for detections and Uploads, a geospatial-context.
   - EID Routing-Sharing hazards, blockages, parking, road-inventory.
   - Compute-First brokerage of geospatial production <> consumption.
   - Predefined EID geospatial mcast channels to subscribed clients.

1. Introduction

   The Locator/ID Separation Protocol (LISP) [I-D.ietf-lisp-rfc6830bis]
   splits IP addresses in two different namespaces, Endpoint Identifiers
   (EIDs) and Routing Locators (RLOCs). LISP uses map-and-encap approach
   (1) a Mapping System (distributed database) that stores and resolves
   EID-RLOC mappings and on (2) LISP tunnel routers (xTRs) encapsulating
    and decapsulating data packets based on content of those mappings.

   H3 (https://h3geo.org)is a geospatial indexing system using hexagonal
   grid that can be subdivided into finer and finer hexagonal grids,
   combining the benefits of a hexagonal grid with hierarchy.
   H3 supports sixteen resolutions. Each finer resolution has cells with
   1/7 the area of the coarser resolution. Hexagons cannot be perfectly
   subdivided into seven hexagons, so the finer cells are approximately
   contained within a parent cell. Each cell is identified by 64bit HID.

The Berkeley Deep Drive (BDD) (https://bdd-data.berkeley.edu) Industry
Consortium investigates computer vision technologies for automotive
applications and for taxonomy of published automotive classification.

These standards are combined to create an in-network state reflecting
condition of each hexagonal tile (~1sqm) in every road. The mobility
H3-LISP network maps & encapsulates traffic between client endpoint
identifiers (EID) and addressable geospatial contexts (H3-HID=>EID).

The H3-LISP mobility network bridges timing and location gaps between
production and consumption of information by clients of mobility data:
 o information producers: vision, sensory, LIADR, AI applications
 o information consumers: driving-apps, map-apps, command & control

This is achieved by putting the physical world on a shared addressable
geospatial context-grid of road-segments represented at the edge.
Geospatial state sharing is done using this brokered-network of tile
representation, an indirection which solves key issues in v2v
information sharing. For example multiple vision perspectives, geo
privacy, cyber security. These challenges arise when clients are
asked to communicate directly when they do not really need to.
A communication pattern which causes complexity and exposures.

In non brokered v2v models, for a situation observable by some end
points, it is unclear if the need-to-know end-points will receive:
i. consistent, ii. conflicting, iii. multiple, or iv. no indications.
As an example, when a vehicle experiences a sudden highway slow-down,
sees brake lights or senses an accelerometer slowdown, there is no
clear way for it to share this data with vehicles 20-30sec away.
Or, when a vehicle crosses an intersection, observing opposite-lane
obstruction such as: construction, double-park, commercial loading,
garbage truck, or stopped school-bus.. there is no clear way for it
to alert approachers from another direction as it drives away.

Geospatial context indirection helps communicate advanced vision and
radar annotations. As these are evolving technologies, relaying road
enumerations using peer-to-peer poses interoperability challenges.

These peer-to-peer limitations are inherent yet unnecessary, in most
situations vehicles are not really proper peers. They happen to be in
the same place at the same time. H3-LISP mobility network solves these
limitations of direct vehicle-to-vehicle communication by brokering
exchanges using addressable geospatial context. Bridging timing,
security, privacy, and interoperability gaps between endpoints.
Brokering is achieved by clients communicating via context,
addressable tiles which aggregated and relay data using H3 EIDs.

Clients can provide drivers with heads-up alerts on hazards/obstacles
beyond the line of sight of driver and in-car sensors: over traffic,
around blocks, far-side junction, beyond road turns or curvatures.
This highlights the importance of networks for road safety
and role in Autonomous Vehicle (AV) operation support (AV-OSS).

To summarize the H3-LISP mobility use-case solution principles are:

(1) MicroPartition: 64bit indexed geo-state per H3.r15 road-tiles
(2) EnumState: 64bit state values of tile condition representation
(3) Grouping: EID per H3.r9 geo-context for its H3.r15 road-tiles
(4) Channels: H3.r9 EIDs multicast address for geo-state updates
(5) Scale: EID addressable contexts distributed for throughput
(6) Overlay: tunneled-network routes the mobility-network traffic
(7) Signal-free: overlay is used to map-register for mcast channels
(8) Layering: overlay tunnels used between client EIDs and H3 EIDs
(9) Access: client/server XTRs tunnel traffic to-from the LISP RTRs
(10) Control: RTRs register-resolve H3 EIDs and mcast subscriptions

```
Figure 1: 64 bit H3 ID, 64 bit compiled state value

Each H3.r9 hexagon is an EID context with corresponding H3 hexagon ID.
Bound to that context is a LISP xTR specified to encapsulate packets
to and from EID context and LISP Edge. Edge RTRs are used to re
-tunnel packets from clients to services. Each service is also a
multicast source for updating clients on the state of the H3.r15
tiles, aggregated by the EID addressable geospatial context.

[2](). Definition of Terms

H3ServiceEID: Is an addressable aggregation of H3.r15 tiles.
    It functions as geospatial data association context for filtering,
    verifying, localizing, and propagating vehicles data uploads.
    It is a designated destination for physical world annotations,
    and an (s,g) source of multicast themed update channels.
    H3ServiceEID is itself an H3 hexagon, large enough to provide
    geo-spatial compute context, but not too large as to over-burden
    subscribers with too much information. For Mobility Network it is
    H3.r9. It has a light-weight LISP protocol stack to tunnel packets
    aka ServerXTR. The EID is an IPv6 EID that contains the H3 64-bit
    address numbering scheme.

ServerXTR: Is a data-plane only LISP protocol stack implementation, it
    co-exists with H3ServiceEID process. When the server roams, the xTR
    is with it. ServerXTR encaps & decaps packets to/from EdgeRTRs.

MobilityClient: Is a roaming application that may be a part of an
    automobile, part of a navigation application, part of municipal,
    state or federal government command and control application, or a
    street view consumer application. It has a light-weight LISP
    data-plane stack to tunnel packets, aka ClientXTR.

MobilityClient EID: Is the IPv6 EID used by the Mobility Clients
    to source packets. The destination of such packets are only
    H3ServiceEIDs. The EID format is opaque and is assigned as
    part of the MobilityClient mobility-network authorization.

ClientXTR: Is a data-plane only LISP protocol stack implementation
    co-located with the Mobility Client application. It encaps/
    decaps packets from/to applications to/from EdgeRTRs.

   EdgeRTR: Is the core scale and structure of the LISP mobility network.
      EdgeRTRs proxy H3ServiceEIDs and MobilityClient H3ServiceEID mcast
      registration. EdgeRTRs aggregate MobilityClients/H3Services using
      tunnels to facilitate hosting-providers and mobile-providers for
      accessing the mobility network. EdgeRTRs decapsulate packets
      from ClientXTRs, ServerXTRs and re-encaps packets to the clients
      and servers tunnels. EdgeRTRs glean H3ServiceEIDs/MobilityClient
      EIDs when they decapsulates packets. EdgeRTRs store H3ServiceEIDs
      and RLOCs of where the H3ServiceEID is currently reachable from
      the map-cache. These mappings are registered to the LISP mapping
      so other EdgeRTRs know where to encapsulate for such EIDs. These
      mappings may be provisioned by dev-ops when H3Services are
      assigned EdgeRTRs. EdgeRTRs do not register MobilityClients' EIDs
      at the mapping as these are temporary-renewed while using the
      mobility network. Enterprises may provide their own EdgeRTRs to
      protect geo-privacy.

Figure 2: H3.r15 state representation, H3.r9 state aggregation

Figure 2 above describes the following entities:
   - MobilityClientA sees MobilityClientB future, and, vice versa
   - Clients: share information using addressable state routed by LISP
   - ClientXTR (cXTR): encapsulates over access network to EdgeRTR
   - ServerXTR (sXTR): encapsulates over cloud network to EdgeRTR
   - H3-LISP Mobility: overlay which spans cXTRs to sXTRs
   - Uploads: routed to appropriate tile by the LISP network
   - EdgeRTRs: perform multicast replication to edges and then cXTRs
   - Clients: receive tile-by-tile geo-state updates via the multicast

3. Deployment Assumptions

   The specification described in this document makes the following
   deployment assumptions:

   (1) Unique 64-bit HID is associated with each H3 geo-spatial tile
   (2) MobilityClients and H3ServiceEIDs share this well known index
   (3) 64-bit BDD state value is associated with each H3-indexed tile
   (4) Tile state is compiled 16 fields of 4-bits, or max 16 enums

```
|-------------------------------------------------------------|
|-0-|-1-|-2-|-3-|-4-|-5-|-6-|-7-|-8-|-9-|-A-|-B-|-C-|-D-|-E-|-F-|

|-------------------------------------------------------------|
```

  Figure 3: Nibble based representation, 16 fields x 16 enumerations

   We name the nibbles using hexadecimal index according to the
   position where the most significant nibble has index 0.
   Values are defined in section 9.

   Subscription of MobilityClients to mobility-network is renewed
   while on the move and is not intended as the basic connectivity.
   MobilityClients use DNS/AAA to obtain temporary EIDs/EdgeRTRs
   and use (LISP) data-plane tunnels to communicate using their
   temporary EIDs with the dynamically assigned EdgeRTRs.

   MobilityClient are otherwise unaware of the LISP network control
   plane and simply regard the data-plane tunnels as a virtual
   private network (VPN) that supports IPv6 EID to upload (Ucast)
   and Subscribe-to (Mcast) H3Services.

In order to get access to the MobilityVPN, MobilityClients first
authenticate with the MobilityVPN AAA Server. DIAMETER [RFC6733]
based AAA is typically done at the provider edge (PE) by gateways.
However, the typical case involves several types of CPE connected
to a specific service provider. The Mobility VPN, on the other hand,
may overlay a number of wireless networks and cloud-edge providers.
It also involves dozens of Car-OEM, Driving-Applications, Smart-
City vendors. This is why we require clients to first go through
AAA in order to get both a MobilityClientEID and EdgeRTR RLOC.

ClientXTR performs the following steps to use the mobility network:
1) obtain the address of the mobility network AAA server using DNS
2) obtain MobilityClientEID and EdgeRTR(s) from AAA DIAMETER server
3) renew authorization from AAA while using the mobility network

```

               |              AAA (Interim)      |               |
```
   Figure 4: DNS and AAA Exchange for nexagon-network login

    Using this network login and re-login method we ensure that:
    - MobilityClientEIDs serve as credentials with the EdgeRTRs
    - EdgeRTRs are provisioned to whitelist MobilityClient EIDs
    - EdgeRTRs are not tightly coupled to H3.r9 areas (privacy/balance)
    - MobilityClients do not need to update EdgeRTRs while roaming

    The same EdgeRTR may serve several H3.r9 areas for ride continuity
    and several EdgeRTRs may load balance an H3.r9 area with high

density of MobilityClients. When a MobilityClient ClientXTR is
homed to EdgeRTR, it is able to communicate with H3ServiceEIDs.

[4](). **Mobility Clients Network Services**

   The mobility network functions as a standard LISP overlay.
   The overlay delivers unicast and multicast packets across:
    - multiple access-networks and radio-access specifications
    - multiple edge providers, public, private, and hybrid clouds

   We use data-plane XTRs in the stack of each mobility client/server.
   ClientXTRs and ServerXTRs are homed to one or more EdgeRTRs.
   This structure allows for MobilityClients to "show up" at any time,
   behind any network provider in a given mobility network admin/NAT
   domain, and for any H3ServiceEID to be instantiated, moved, or
   failed-over to any rack in any cloud-provider. LISP overlay enables
   these roaming mobility network elements to communicate uninterrupted.
   This quality is insured by the LISP RFCs. The determination of
   identities for MobilityClients to always refer to the correct
   H3ServiceEID is insured by H3 geo-spatial HIDs.

   There are two options to associate ClientXTRs with LISP EdgeRTRs:

   i. Semi-random load-balancing by DNS/AAA

   In this option we assume that in a given metro edge a pool of
   EdgeRTRs can distribute the Mobility Clients load randomly between
   them and that EdgeRTRs are topologically equivalent. Each RTR uses
   LISP to tunnel traffic to and from other EdgeRTRs for MobilityClient
   with H3Service exchanges. MobilityClients home to EdgeRTRs.

   ii. Topological by anycast

   In this option we align an EdgeRTR with topological aggregation.
   Mobility Clients are roaming in an area home to that RTR and so
   is the H3 Server. There is only one hop across the edge overlay
   between clients and servers and mcast replication is more
   focused, but clients need to keep re-homing as they move.

To summarize the H3LISP mobility network layout:

   (1) Mobility-Clients traffic is tunneled via data-plane ClientXTRs
       ClientXTRs are (multi) homed to EdgeRTR(s)
   (2) H3ServiceEID traffic is tunneled via data-plane ServerXTR
       ServerXTRs are (multi) homed to EdgeRTR(s)
   (3) EdgeRTRs use mapping service to resolve Ucast HIDs to RTR RLOCs
       EdgeRTRs also register to (Source, Group) H3ServiceEID multicasts

       MobilityClients <> ClientXTR <Access Provider > EdgeRTR v
                                                                v
       v < < < < Map-Assisted Mobility-Network Overlay < < < < v
       v
       > > > > EdgeRTR <Cloud Provider> ServerXTR <> H3ServiceEID

   Figure 5: The Data Flow Between MobilityClients and H3ServiceEIDs

5. Mobility Unicast and Multicast

   Regardless of the way a given ClientXTR was associated with EdgeRTR,
   an authenticated MobilityClient EID can send: [64bitH3.15ID ::
   64bitState]annotations to the H3.r9 H3ServiceEID. The H3.r9 EID can
   be calculated by clients algorithmically from the H3.15 localization.

   The ClientXTR encapsulates MobilityClient EID and H3ServiceEID from
   the ClientXTR with the destination of the EdgeRTR RLOC LISP port.
   EdgeRTRs then re-encapsulate annotation packets either to a remote
   EdgeRTR (option 1) or to homed H3ServiceEID ServerXTR (option 2).
   The remote EdgeRTR aggregating H3ServiceEIDs re-encapsulates
   MobilityClient EID to the ServerXTR, to the H3ServiceEID.

   The headers consist of the following fields:

   Outer headers = 40 (IPv6) + 8 (UDP) + 8 (LISP) = 56
   Inner headers = 40 (IPv6) + 8 (UDP) + 4 (Nexagon Header) = 52
   1500 (MTU) - 56 - 52 = 1392 bytes of effective payload

   Nexagon Header Type allows for kv tupples of vkkk flooding
   Type 0: reserved
   Type 1:key-value, key-value.. 1392 / (8 + 8) = 87 pairs

Figure 6: Uploaded detections packet format

To Summarize Unicast:

   (1) MobilityClients can send annotations are localized to H3.r15
       tile. These annotations are sent to H3.r9 mobility H3ServiceEIDs
   (2) MobilityClient EID and H3ServiceEID HID are encapsulated:
          XTR <> RTR <> RTR <> XTR
       * RTRs can map-resolve re-tunnel HIDs
   (3) RTRs re-encapsulate original source-dest to ServerXTRs
       ServerXTRs decapsulate packets to H3ServiceEID

   Each H3.r9 Server is also an IP Multicast Source used to update
   subscribers on the aggregate state of the H3.r15 tiles in the H3.r9
   server. This forms a multipoint to multipoint state channel per H3
   location, where the aggregation has compute-first propagation.

   We use [RFC8378] signal-free multicast to implement mcast channels in
   the overlay. The mobility network has many channels, with thousands
   subscribers per channel. MobilityClients driving through/subscribing
   to an H3.r9 area can explicitly issue an [RFC4604] MLDv2 in order to
   subscribe, or, may be subscribed implicitly by the EdgeRTR.

   The advantage of explicit client MLDv2 registration as [RFC8378]
   trigger is that clients manage their own mobility mcast handover per
   location-direction vectors, and that it allows for otherwise silent
   non annotating clients. The advantage of EdgeRTR implicit registration
   is that less signaling required.

   MLDv2 signaling messages are encapsulated between the ClientXTR and
   EdgeRTR, therefore there is no requirement for the underlying network
   to support native multicast. If native access multicast is supported
   then MobilityClient registration to H3ServiceEID safety channels may
   be integrated with it, in which case mobile packet-core element
   supporting it will use this standard to register with the
   appropriate H3.r9 channels in its area.

Multicast update packets are of the following structure:

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1

   Figure 9: Mcast update payload, value, key, key.. for larger areas

   The remote EdgeRTRs homing MobilityClients in turn replicate the
   packet to the MobilityClients registered with them.

   We expect an average of 600 H3.r15 tiles of the full 7^6 (~100K)
   possible in H3.r9 to be part of any road. The H3.r9 server can
   transmit the status of all 600 or just those with meaningful states
   based on updated SLA and policy.

   To Summarize:

    (1) H3LISP Clients tune to H3.r9 mobility updates using [RFC8378]
        H3LISP Client issue MLDv2 registration to H3.r9 HIDs
        ClientXTRs encapsulate MLDv2 to EdgeRTRs who register (s,g).

    (2) ServerXTRs encapsulate updates to EdgeRTRs who map-resolve (s,g)
        RLOCs EdgeRTRs replicate mobility update and tunnel to registered
        EdgeRTRs Remote EdgeRTRs replicate updates to ClientXTRs.

6. Security Considerations

   The nexagon layer3 v2n network is inherently more secure and private
   then peer to peer alternatives because of the indirection. No car or
   infrastructure element communicates directly with MobilityClients.
   All information is conveyed using shared addressable geo-state.
   MobilityClients receive information only from geospatial channels
   originating from a trusted broker. MobilityClients have no indication
   as to the origin of the information. This is an important step towards
   better privacy, security, extendability, and interoperability compared
   with legacy layer2 protocols.

   In order to be able to use the nexagon mobility network for a given
   period, the mobility clients go through a DNS/AAA stage by which they
   obtain their clientEID identifiers-credentials and the RLOCs of
   EdgeRTRs they may use as gateways to the network. This MobilityClient
   <> EdgeRTR interface is the most sensitive in this network to privacy
   and security considerations.

   The traffic on the MobilityClient<>EdgeRTR interface is tunneled, and
   its UDP content may be encrypted; still, the EdgeRTR will know based
   on the LISP headers alone the MobilityClient RLOC and H3-R9 (~0.1sqkm)
   geo-spatial area to which a given client uploads or subscribes to.

   For this reason we envision the ability of enterprise or groups of
   users to "bring their own" EdgeRTRs. BYO-RTR masks individual clients'
   RLOC to H3-R9 association and is pre-provisioned to be able to use the
   mapping system and be on a white-list of EdgeRTRs aggregating
   H3ServiceEIDs. If the EdgeRTR functionality is delivered by 5GCore UPF
   then the only entity which can correlate underlay IP, User, and Geo-
   location is the regulated carrier, which can do so anyway.

   Beyond this hop, the mapping system does not hold MobilityClientEIDs,
   and remote EdgeRTRs are only aware of MobilityClient ephemeral EIDs,
   not actual RLOC or any other mobile-device identifiers. EdgeRTRs
   register in the mapping (s,g) H3-R9 multicast groups. Which clients
   use which EdgeRTR is not in the mapping system, only the AAA server is
   aware of that. The H3ServiceEIDs themselves decrypt and parse actual
   H3-R15 annotations; they also consider during this MobilityClientEID
   credentials to avoid "fake-news", but again these are only temporary
   EIDs allocated to clients in order to be able to use the mobility
   network and not for their actual IP.

   H3Services are provisioned to their EdgeRTRs, in the EdgeRTRs, and
   optionally also in the mapping system.

In summary of main risk mitigations for the lisp-nexagon interface:

(1) tapping: all communications are through dynamic tunnels therefore
may be encrypted using IP-Sec or other supported point to point
underlay standards. These are not static tunnels but LISP re-tunneling
routers (RTRs) perform all nexagon Overlay aggregation.

(2) spoofing: it is very hard to guess a MobilityClientEID valid for
a short period of time. Clients and H3Services EIDs are whitelisted
in EdgeRTRs, Clients using the AAA procedure, H3Services via dev-ops.

(3) impersonating: efforts to use MobilityClients and H3Services RLOCs
should be caught by the underlying service provider edge and access
networks. EID impersonating is caught by EdgeRTR EID RLOC whitelist
mismatch.

(4) credibility: the interface crowd-sources geo-state and does not
assume to trust single detections. Credit history track to
MobilityClientEIDs by as part of normal H3Services fact checking,
aggregate scores affect AAA credentials.

(5) privacy: Only EdgeRTRs are aware of both clients' RLOC and
geo-location, only AAA is aware of client IDs credentials and credit
but not geo-location. Aggregate credit score span all H3Services
administratively without source.

7. Acknowledgments

[8](#). **IANA Considerations**

   This section provides guidance to the Internet Assigned Numbers
   Authority (IANA) regarding enumeration of road-tile (H3.r15) values.
   These enumerations are organized as 16 x nibbles = 64bits, a compact
   bit-mask which aligns with 64bit H3IDs. The 5 last fields 0xB, 0xC,
   0xD, 0xE remain unassigned for future specification of AV support
   enumeration such as platoon-join tiles, pull-over tiles, etc.

State enum fields of H3 tiles:

Field 0x0: Traffic Direction {
0x0 - null
0x1 - Lane North
0x2 - Lane North + 30
0x3 - Lane North + 60
0x4 - Lane North + 90
0x5 - Lane North + 120
0x6 - Lane North + 150
0x7 - Lane North + 180
0x8 - Lane North + 210
0x9 - Lane North + 240
0xA - Lane North + 270
