**Multi-path Extension for the Optimized Link State Routing Protocol  
version 2 (OLSRv2)  
draft-ietf-manet-olsrv2-multipath-07**

**Abstract**

This document specifies a multi-path extension for the Optimized Link State Routing Protocol version 2 (OLSRv2) to discover multiple disjoint paths, so as to improve reliability of the OLSRv2 protocol. The interoperability with OLSRv2 is retained.

**Status of this Memo**

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on July 23, 2016.

## **1. Introduction**

The Optimized Link State Routing Protocol version 2 (OLSRv2) [[RFC7181](#)] is a proactive link state protocol designed for use in mobile ad hoc networks (MANETs). It generates routing messages periodically to create and maintain a Routing Set, which contains routing information to all the possible destinations in the routing domain. For each destination, there exists a unique Routing Tuple, which indicates the next hop to reach the destination.

This document specifies an extension of the OLSRV2 protocol [[RFC7181](#)], to provide multiple disjoint paths when appropriate for a source-destination pair. Because of the characteristics of MANETs [[RFC2501](#)], especially the dynamic topology, having multiple paths is helpful for increasing network throughput, improving forwarding reliability and load balancing.

The Multi-path OLSRV2 (MP-OLSRv2) specified in this document uses Multi-path Dijkstra algorithm by default to explore multiple disjoint paths from a source router to a destination router based on the topology information obtained through OLSRV2, and to forward the datagrams in a load-balancing manner using source routing. MP-OLSRv2 is designed to be interoperable with OLSRV2.

### **1.1. Motivation and Experiments to Be Conducted**

This document is an experimental extension of OLSRV2 that can increase the data forwarding reliability in dynamic and high-load MANET scenarios by transmitting datagrams over multiple disjoint paths using source routing. This mechanism is used because:

- o Disjoint paths can avoid single route failures.
- o Transmitting datagrams through parallel paths can increase aggregated throughput and provide load balancing.
- o Certain scenarios require some routers must (or must not) be used.
- o By having control of the paths at the source, the delay can be provisioned.
- o A very important application of this extension is in combination with Forward Error Correction (FEC) coding. Because the packet drop is normally bursty in a path (for example, due to route failure), FEC coding is less effective in single path routing protocols. By providing multiple disjoint paths, the application of FEC coding with multi-path protocol is more resilient to routing failures.

While in existing deployments, running code and simulations have proven the interest of multi-path extension for OLSRv2 in certain networks, more experiments and experiences are still needed to understand the effects of the protocol. The multi-path extension for OLSRv2 is expected to be revised and improved to the Standard Track, once sufficient operational experience is obtained. Other than general experiences including the protocol specification, interoperability with original OLSRv2 implementations, the experiences in the following aspects are highly appreciated:

- o Optimal values for the number of multiple paths (NUMBER\_OF\_PATHS) to be used. This depends on the network topology and router density.
- o Optimal values used in the metric functions. Metric functions are applied to increase the metric of used links and nodes so as to obtain disjoint paths. What kind of disjointness is desired (node-disjoint or link-disjoint) may depend on the layer 2 protocol used, and can be achieved by setting different sets of metric functions.
- o Use of other metric types. This multi-path extension can be used not only for hop-count metric type, but also other metric types that meet the requirement of OLSRv2, such as [[I-D.ietf-manet-olsrv2-dat-metric](#)]. The metric type used has also co-relation with the choice of metric functions as indicated in the previous bullet point.
- o Optimal choice of "key" routers for loose source routing. In some cases, loose source routing is used to reduce overhead or for interoperability with OLSRv2 routers. Other than the basic rules defined in the following of this document, optimal choices of routers to put in the loose source routing header can be further studied.
- o Different path-selection schedulers. By default, Round-Robin scheduling is used to select a path to be used for datagrams. In some scenarios, weighted scheduling can be considered: for example, the paths with lower metrics (i.e., higher quality) can transfer more datagrams compared to paths with higher metrics.
- o The impacts of the delay variation due to multi-path routing. [[RFC2991](#)] brings out some concerns of multi-path routing, especially variable latencies. Although current experiment results show that multi-path routing can reduce the jitter in dynamic scenarios, some transport protocols or applications may be sensitive to the datagram re-ordering.

- o The disjoint multi-path protocol has interesting application with Forward Error Correction (FEC) Coding, especially for services like video/audio streaming. The combination of FEC coding mechanisms and this extension is thus encouraged. By applying FEC coding, the issue of packet re-ordering can be alleviated.
- o Different algorithms to obtain multiple paths, other than the default Multi-path Dijkstra algorithm introduced in this specification.
- o The use of multi-topology information. By using [[RFC7722](#)], multiple topologies using different metric types can be obtained. It is also encouraged to experiment the use of multiple metrics for building multiple paths.

## 2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

This document uses the terminology and notation defined in [[RFC5444](#)], [[RFC6130](#)], [[RFC7181](#)]. Additionally, it defines the following terminology:

OLSRV2 Routing Process - The routing process based on [[RFC7181](#)], without multi-path extension specified in this document.

MP-OLSRV2 Routing Process - The multi-path routing process based on this specification as an extension to [[RFC7181](#)].

## 3. Applicability Statement

As an extension of OLSRV2, this specification is applicable to MANETs for which OLSRV2 is applicable (see [[RFC7181](#)]). It can operate on single, or multiple interfaces, to discover multiple disjoint paths from a source router to a destination router.

MP-OLSRV2 is specially designed for networks with dynamic topology and low data rate links. By providing multiple paths, higher aggregated throughput can be obtained, and the routing process is more robust to packet loss.

In a router supporting MP-OLSRV2, MP-OLSRV2 does not necessarily replace OLSRV2 completely. The extension can be applied for certain

applications that are suitable for multi-path routing (mainly video or audio streams), based on the information such as DiffServ Code Point [[RFC2474](#)].

Compared to OLSRV2, this extension does not introduce new message type in the air. A new Message TLV type is introduced to identify the routers that support forwarding based on source route header. It is interoperable with OLSRV2 implementations that do not have this extension.

MP-OLSRV2 forwards datagrams using the source routing header. For IPv4 networks, implementation of loose source routing is required following [[RFC0791](#)]. For IPv6 networks, implementation of strict source routing is required following [[RFC6554](#)].

#### **4. Protocol Overview and Functioning**

This specification requires OLSRV2 [[RFC7181](#)] to:

- o Identify all the reachable routers in the network.
- o Identify a sufficient subset of links in the networks, so that routes can be calculated to all reachable destinations.
- o Provide a Routing Set containing shortest routes from this router to all destinations.

In addition, the MP-OLSRV2 Routing Process identifies the routers that support source routing by adding a new Message TLV in HELLO and TC messages. Based on the above information acquired, every MP-OLSRV2 Routing Process is aware of a reduced topology map of the network and the routers supporting source routing.

A multi-path algorithm is invoked on demand, i.e., only when there is a datagram to be sent from the source to the destination, and there is no available routing tuple in the Multi-path Routing Set. The Multi-path Dijkstra algorithm (defined in [Section 8.5](#)) can generate multiple disjoint paths from a source to a destination, and such information is kept in the Multi-path Routing Set.

The datagram is forwarded based on source routing. When there is a datagram to be sent to a destination, the source router acquires a path from the Multi-path Routing Set (MAY be Round-Robin, or other scheduling algorithms). The path information is stored in the datagram header as source routing header.

## 5. Parameters and Constants

In addition to the parameters and constants defined in [\[RFC7181\]](#), this specification uses the parameters and constants described in this section.

### 5.1. Router Parameters

**NUMBER\_OF\_PATHS** The number of paths desired by the router.

**MAX\_SRC\_HOPS** The maximum number of hops allowed to be put in the source routing header. A value set zero means there is no limitation on the maximum number of hops. In an IPv6 network, it MUST be set to 0. In an IPv4 network, it MUST be strictly less than 11.

**CUTOFF\_RATIO** The ratio that defines the maximum metric of a path compared to the shortest path kept in the OLSRv2 Routing Set. For example, the metric to a destination is  $R\_metric$  based on the Routing Set. Then the maximum metric allowed for a path is  $CUTOFF\_RATIO * R\_metric$ . **CUTOFF\_RATIO** MUST be strictly greater than 1.

**SR\_TC\_INTERVAL** The maximum time between the transmission of two successive TC messages by a MP-OLSRv2 Routing Process.

**SR\_OLSR\_HOLD\_TIME** It is the minimal time that a SR-OLSRv2 Router Tuple SHOULD be kept in the SR-OLSRv2 Router Set.

## 6. Packets and Messages

This extension employs the routing control messages HELLO and TC (Topology Control) as defined in OLSRv2 [\[RFC7181\]](#). To support source routing, a source routing header is added to each datagram routed by this extension. Depending on the IP version used, the source routing header is defined in this section.

### 6.1. HELLO and TC messages

HELLO and TC messages used by MP-OLSRv2 Routing Process share the same format as defined in [\[RFC7181\]](#). In addition, a new Message TLV type is defined, to identify the originator of the HELLO or TC message that supports source route forwarding. The new Message TLV type is introduced for enabling MP-OLSRv2 as an extension of OLSRv2: only the routers supporting source-route forwarding can be used in the source routing header of a datagram, because adding a router that does not understand the source routing header will cause routing

failure.

#### **6.1.1. SOURCE\_ROUTE TLV**

SOURCE\_ROUTE TLV is a Message TLV signalling that the message is generated by a router that supports source-route forwarding. It can be an MP-OLSRv2 Routing Process, or an OLSRv2 Routing Process that supports source-route forwarding. The SOURCE\_ROUTE TLV does not include any value.

Every HELLO or TC message generated by a MP-OLSRv2 Routing Process MUST have exactly one SOURCE\_ROUTE TLV.

Every HELLO or TC message generated by an OLSRv2 Routing Process MAY have one SOURCE\_ROUTE TLV, if the OLSRv2 Routing Process supports source-route forwarding, and is willing to join the source route generated by other MP-OLSRv2 Routing Processes. The existence of SOURCE\_ROUTE TLV MUST be consistent for a specific OLSRv2 Routing Process, i.e., either it adds SOURCE\_ROUTE TLV to all its HELLO/TC messages, or it does not add SOURCE\_ROUTE TLV to any HELLO/TC message.

### **6.2. Datagram**

#### **6.2.1. Source Routing Header in IPv4**

In IPv4 [[RFC0791](#)] networks, the MP-OLSRv2 routing process employs loose source routing header, as defined in [[RFC0791](#)]. It exists as an option header, with option class 0, and option number 3.

The source route information is kept in the "route data" field of the loose source route header.

#### **6.2.2. Source Routing Header in IPv6**

In IPv6 [[RFC2460](#)] networks, the MP-OLSRv2 routing process employs the source routing header as defined in [[RFC6554](#)], with IPv6 Routing Type 3.

The source route information is kept in the "Addresses" field of the routing header.

### **7. Information Bases**

Each MP-OLSRv2 routing process maintains the information bases as defined in [[RFC7181](#)]. Additionally, two more information bases are defined for this specification.

### **7.1. SR-OLSRv2 Router Set**

The SR-OLSRv2 Router Set records the routers that support source-route forwarding. This includes routers that run MP-OLSRv2 Routing Process, or OLSRv2 Routing Process with source-route forwarding support. The set consists of SR-OLSRv2 Router Tuples:

(SR\_OLSR\_addr, SR\_OLSR\_valid\_time)

where:

SR\_OLSR\_addr - it is the network address of the router that supports source-route forwarding;

SR\_OLSR\_valid\_time - it is the time until which the SR-OLSRv2 Router Tuples is considered valid.

### **7.2. Multi-path Routing Set**

The Multi-path Routing Set records the full path information of different paths to the destination. It consists of Multi-path Routing Tuples:

(MR\_dest\_addr, MR\_path\_set)

where:

MR\_dest\_addr - it is the network address of the destination, either the network address of an interface of a destination router or the network address of an attached network;

MP\_path\_set - it contains the multiple paths to the destination. It consists of a set of Path Tuples.

Each Path Tuple is defined as:

(PT\_metric, PT\_address[1], PT\_address[2], ..., PT\_address[n])

where:

PT\_metric - the metric of the path to the destination, measured in LINK\_METRIC\_TYPE defined in [\[RFC7181\]](#);

PT\_address[1...n] - the addresses of intermediate routers to be visited numbered from 1 to n.

## 8. Protocol Details

This protocol is based on OLSRv2, and extended to discover multiple disjoint paths from a source router to a destination router. It retains the basic routing control packets formats and processing of OLSRv2 to obtain topology information of the network. The main differences between OLSRv2 routing process are the datagram processing at the source router and datagram forwarding.

### 8.1. HELLO and TC Message Generation

HELLO messages are generated according to the [Section 15.1 of \[RFC7181\]](#).

TC message are generated according to the [Section 16.1 of \[RFC7181\]](#). As least one TC message MUST be generated by an MP-OLSRv2 Routing Process during SR\_TC\_INTERVAL.

For both TC and HELLO messages, a single Message TLV with Type := SOURCE\_ROUTE MUST be added to the message.

### 8.2. HELLO and TC Message Processing

HELLO and TC messages are processed according to the [section 15.3 and 16.3 of \[RFC7181\]](#).

For every HELLO or TC message received, if there is a Message TLV with Type := SOURCE\_ROUTE, create or update (if the tuple exists already) the SR-OLSR Router Tuple with

- o SR\_OLSR\_addr := originator of the HELLO or TC message
- o SR\_OLSR\_valid\_time := current\_time + SR\_OLSR\_HOLD\_TIME.

### 8.3. MPR Selection

Each MP-OLSRv2 Routing Process selects routing MPRs and flooding MPRs following [Section 18 of \[RFC7181\]](#). In a mixed network with OLSRv2-only routers, the following considerations apply when calculating MPRs:

- o MP-OLSR routers SHOULD be preferred as routing MPRs.
- o The number of routing MPRs that run MP-OLSR Routing Process MUST be equal or greater than NUMBER\_OF\_PATHS if there are enough MP-OLSR symmetric neighbors. Or else, all the MP-OLSR routers are selected as routing MPRs.

#### **8.4. Datagram Processing at the MP-OLSRv2 Originator**

If datagrams without source routing header need to be forwarded using multiple paths (for example, based on the information of DiffServ Code Point [[RFC2474](#)]), the MP-OLSRv2 routing process will try to find the Multi-path Routing Tuple where:

- o MR\_dest\_addr = destination of the datagram

If no matching Multi-path Routing Tuple is found, the multi-path algorithm defined in [Section 8.5](#) is invoked, to calculate the Multi-path Routing Tuple to the destination. If the calculation does not return any Multi-path Routing Tuple, the following steps are aborted and the datagram is forwarded following OLSRv2 routing process.

The Path Tuples of the Multi-path Routing Tuple obtained are applied to the datagrams using Round-robin scheduling. For example, they are 2 path tuples (Path-1, Path-2) for destination router D. A series of datagrams (Packet-1, Packet-2, Packet-3, ... etc.) are to be sent router D. Path-1 is then chosen for Packet-1, Path-2 for Packet-2, Path-1 for Packet 3, etc.

The addresses in PT\_address[1...n] of the chosen Path Tuple are thus added to the datagram header as the source routing header. For IPv6 networks, strict source routing is used, thus all the intermediate routers in the path are stored in the source routing header following [[RFC6554](#)]. For IPv4 networks, loose source routing is used, with following rules:

- o Only the addresses that exist in SR-OLSR Router Set can be added to the source routing header.
- o If the length of the path (n) is greater than MAX\_SRC\_HOPS, only the "key" routers in the path are kept. The key routers can be chosen based on the capacity of the routers (e.g., battery life) or the router's willingness in forwarding data. If no such information is available, the key routers are uniformly chosen in the path.
- o The routers that are considered not appropriate for forwarding indicated by external policies should be avoided.

#### **8.5. Multi-path Calculation**

##### **8.5.1. Requirements of Multi-path Calculation**

The Multi-path Routing Set maintains the information of multiple paths to the destination. The tuples are generated based on a

multi-path algorithm.

A multi-path algorithm is invoked when there is no available Multi-path Routing Tuple to a desired destination to obtain the multiple paths. For each path to a destination, the algorithm must provide:

- o The metric of the path to the destination,
- o The list of intermediate routers on the path.

For IPV6 networks, as strict source routing is used, only the routers that exist in SR-OLSRV2 Router Set are considered in the path calculation, i.e., only the source-routing supported routers can exist in the path. After the calculation of multiple paths, the metric of the shortest path (denoted  $c$ ) to the destination is compared to the  $R\_metric$  of the OLSRV2 Routing Tuple ([\[RFC7181\]](#)) to the same destination. If the metric  $c$  is greater than  $R\_metric * CUTOFF\_RATIO$ , the multipath routing SHOULD NOT be used, and the router SHOULD fall back to OLSRV2 Routing Process. This can happen if there are too much OLSRV2-only routers in the network, and requiring multipath routing brutally may result in inferior paths.

By invoking the multi-path algorithm,  $NUMBER\_OF\_PATHS$  paths are obtained and added to the Multi-path Routing Set, by creating a Multi-path Routing Tuple with:

- o  $MR\_dest\_addr$  := destination of the datagram
- o A  $MP\_path\_set$  with calculated Path Tuples. Each Path Tuple corresponds to a path obtained in Multi-path Dijkstra algorithm, with  $PT\_metric$  := metric of the calculated path and  $PT\_address[1..n]$  := list of intermediate routers.

### **8.5.2. Multi-path Dijkstra Algorithm**

This section introduces Multi-path Dijkstra Algorithm as a default algorithm. It tries to obtain disjoint paths when appropriate, but does not guarantee strict disjoint paths. The use of other algorithms is not prohibited, as long as the requirements described in [Section 8.5.1](#) are met. Using different multi-path algorithms will not impact the interoperability.

The general principle of the Multi-path Dijkstra Algorithm is at step  $i$  to look for the shortest path  $P[i]$  to the destination  $d$ . Compared to the original Dijkstra algorithm, the main modification consists in adding two incremental functions named metric functions  $fp$  and  $fe$  in order to prevent the next steps resulting in similar paths:

- o  $fp(c)$  is used to increase metrics of arcs belonging to the previous path  $P[i-1]$  (with  $i>1$ ), where  $c$  is the value of the previous metric. This encourages future paths to use different arcs but not different vertices.
- o  $fe(c)$  is used to increase metrics of the arcs who lead to intermediate vertices (i.e., the source and destination are not considered) of the previous path  $P[i-1]$  (with  $i>1$ ), where  $c$  is the value of the previous metric.

It is possible to choose different  $fp$  and  $fe$  to get link-disjoint paths or node-disjoint paths as desired. A recommendation of configuration of  $fp$  and  $fe$  is given in [Section 9](#).

To get `NUMBER_OF_PATHS` different paths, for each path  $P[i]$  ( $i = 1, \dots, \text{NUMBER\_OF\_PATHS}$ ) do:

1. Run Dijkstra algorithm to get the shortest path  $P[i]$  for the destination  $d$ .
2. Apply metric function  $fp$  to the metric of links (in both directions) in  $P[i]$ .
3. Apply metric function  $fe$  to the metric of links (in both directions) that lead to routers used in  $P[i]$ .

A simple example of Multi-path Dijkstra Algorithm is illustrated in [Appendix A](#).

### **8.6. Datagram Forwarding**

In IPv4 networks, datagrams are forwarded using loose source routing as specified in [Section 3.1 of \[RFC0791\]](#).

In IPv6 networks, datagrams are forwarded using strict source routing as specified in [Section 4.2 of \[RFC6554\]](#).

## **9. Configuration Parameters**

This section gives default values and guideline for setting parameters defined in [Section 5](#). Network administrators may wish to change certain, or all the parameters for different network scenarios. As an experimental track protocol, the users of this protocol are also encouraged to explore different parameter setting in various network environments, and provide feedback.

- o `NUMBER_OF_PATHS := 3`. This parameter defines the number of parallel paths used in datagram forwarding. Setting it to one makes the specification identical to OLSRv2. Setting it to too large values may lead to unnecessary computational overhead and inferior paths.
- o `MAX_SRC_HOPS := 10`, for IPv4 networks. For IPv6 networks, it MUST be set to 0, i.e., no constraint on maximum number of hops.
- o `CUTOFF_RATIO := 1.5`. It MUST be strictly greater than 1.
- o `SR_TC_INTERVAL := 10 x TC_INTERVAL`. It SHOULD be significantly greater than `TC_INTERVAL` to reduce unnecessary TC message generations.
- o `SR_OLSR_HOLD_TIME := 3 x SR_TC_INTERVAL`

If Multi-path Dijkstra Algorithm is applied:

- o `fp(c) := 4*c`, where `c` is the original metric of the link.
- o `fe(c) := 2*c`, where `c` is the original metric of the link.

The setting of metric functions `fp` and `fc` defines the preference of obtained multiple disjoint paths. If `id` is the identity function, i.e., `fp(c)=c`, 3 cases are possible:

- o if `id=fe<fp`: paths tend to be link disjoint;
- o if `id<fe=fp`: paths tend to be node-disjoint;
- o if `id<fe<fp`: paths also tend to be node-disjoint, but when is not possible they tend to be arc disjoint.

## **10. Implementation Status**

This section records the status of known implementations of the protocol defined by this specification at the time of posting of this Internet-Draft, and based on a proposal described in [[RFC6982](#)]. The description of implementations in this section is intended to assist the IETF in its decision processes in progressing drafts to RFCs. Please note that the listing of any individual implementation here does not imply endorsement by the IETF. Furthermore, no effort has been spent to verify the information presented here that was supplied by IETF contributors. This is not intended as, and must not be construed to be, a catalog of available implementations or their features. Readers are advised to note that other implementations may

exist.

According to [RFC6982], "this will allow reviewers and working groups to assign due consideration to documents that have the benefit of running code, which may serve as evidence of valuable experimentation and feedback that have made the implemented protocols more mature. It is up to the individual working groups to use this information as they see fit".

Until April 2015, there are 3 open source implementations of the protocol specified in this document, for both testbed and simulation use.

#### **10.1. Multi-path extension based on nOLSRv2**

The implementation is conducted by University of Nantes, France, and is based on Niigata University's nOLSRv2 implementation. It is an open source implementation. The code is available at [https://github.com/yijiazi/mpolsr\\_qualnet](https://github.com/yijiazi/mpolsr_qualnet) and <http://jiiaziyi.com/index.php/research-projects/mp-olsr> .

It can be used for Qualnet simulations, and be exported to run in a testbed. All the specification is implemented in this implementation.

Implementation experience and test data can be found at [ADHOC11].

#### **10.2. Multi-path extension based on olsrd**

The implementation is conducted under SEREADMO (Securite des Reseaux Ad Hoc & Mojette) project, and supported by French research agency (RNRT2803). It is based on olsrd (<http://www.olsr.org/>) implementation, and is open sourced. The code is available at [https://github.com/yijiazi/mpolsr\\_testbed](https://github.com/yijiazi/mpolsr_testbed) and <http://jiiaziyi.com/index.php/research-projects/sereadmo> .

The implementation is for testing the specification in the field. All the specification is implemented in this implementation.

Implementation experience and test data can be found at [ADHOC11] and [GIIS14].

#### **10.3. Multi-path extension based on umOLSR**

The implementation is conducted by University of Nantes, France, and is based on um-olsr implementation (<http://masimum.inf.um.es/fjrm/development/um-olsr/>). The code is available at [https://github.com/yijiazi/mpolsr\\_ns2](https://github.com/yijiazi/mpolsr_ns2) and

<http://jiazyi.com/index.php/research-projects/mp-olsr> under GNU GPL license.

The implementation is for network simulation for NS2 network simulator. All the specification is implemented in this implementation.

Implementation experience and test data can be found at [\[WCNC08\]](#).

## **11. Security Considerations**

As an extension of [\[RFC7181\]](#), the security considerations and security architecture illustrated in [\[RFC7181\]](#) are applicable to this MP-OLSRv2 specification. The implementations without security mechanisms are vulnerable to threats discussed in [\[I-D.ietf-manet-olsrv2-sec-threats\]](#).

In a mixed network with OLSRv2-only routers, a compromised router can add SOURCE\_ROUTE TLVs in its TC and HELLO messages, which will make other MP-OLSR Routing Process believes that it supports source routing. This will increase the the possibility of being chosen as MPRs and be put into the source routing header. The former will make it possible to manipulate the flooding of TC messages and the latter will make the datagram pass through the compromised router.

As [\[RFC7181\]](#), a conformant implementation of MP-OLSRv2 MUST, at minimum, implement the security mechanisms specified in [\[RFC7183\]](#) to provide integrity and replay protection of routing control messages.

Compared to OLSRv2, the use of source routing header in this specification introduces vulnerabilities related to source routing attacks, which include bypassing filtering devices, bandwidth exhaustion of certain routers, etc. Those attacks are discussed in [Section 5.1 of \[RFC6554\]](#) and [\[RFC5095\]](#).

## **12. IANA Considerations**

This section adds one new Message TLV, allocated as a new Type Extension to an existing Message TLV.

### **12.1. Expert Review: Evaluation Guidelines**

For the registry where an Expert Review is required, the designated expert SHOULD take the same general recommendations into consideration as are specified by [\[RFC5444\]](#).

## 12.2. Message TLV Types

This specification updates the Message Type 7 by adding the new Type Extension SOURCE\_ROUTE, as illustrated in Table 1.

Type	Name	Description	Reference
Extension			
TBD	SOURCE_ROUTE	Indicates the originator of the message supports source route forwarding. No value.	This specification

Table 1: SOURCE\_ROUTE type for [RFC 5444](#) Type 7 Message TLV Type Extensions

## 13. Acknowledgments

The authors would like to thank Sylvain David, Asmaa Adnane, Eddy Cizeron, Salima Hama, Pascal Lesage and Xavier Lecourtier for their efforts in developing, implementing and testing the specification. The authors also appreciate valuable comments and discussions from Thomas Clausen, Ulrich Herberg, Justin Dean, Geoff Ladwig, Henning Rogge, Christopher Dearlove and Marcus Barkowsky.

## **[Appendix A.](#) Examples of Multi-path Dijkstra Algorithm**

This appendix gives two examples of multi-path Dijkstra algorithm.

A network topology is depicted in Figure 1.

Figure 1

The capital letters are name of routers. An arbitrary metric with value between 1 and 3 is used. The initial metrics of all the links are indicated in the parenthesis. The incremental functions  $fp$  and  $fe$  are defined as  $fp(c)=4c$  and  $fe(c)=2c$  in this example. Two paths from router S to router D are demanded.

On the first run of the Dijkstra algorithm, the shortest path S->A->D with metric 3 is obtained.

The incremental function  $fp$  is applied to increase the metric of the link S-A and A-D.  $fe$  is applied to increase the metric of the link A-B and A-C. Figure 2 shows the link metrics after the punishment.

Figure 2

On the second run of the Dijkstra algorithm, the second path S->B->C->D with metric 6 is obtained.

As mentioned in [Section 8.5](#), the Multi-path Dijkstra Algorithm does not guarantee strict disjoint path to avoid choosing inferior paths. For example, given the topology in Figure 3, two paths from node S to D are desired. On the top of the figure, there is a high cost path between S and D.

If a algorithm tries to obtain strict disjoint paths, the two paths obtained will be S--B--D and S--(high cost path)--D, which are extremely unbalanced. It is undesired because it will cause huge delay variance between the paths. By using the Multi-path Dijkstra

algorithm, which is based on the punishing scheme, S--B--D and S--B--C--D will be obtained.
